"The auriferous gravels of California . . . probably cover an area about equal to that occupied by the auriferous gravels of Seward Peninsula, but the Klondike goldfield is probably less than one-tenth as large. The California placers are not only ideally located for economic exploitation, but their gold content averaged no less than that of the Seward Peninsula gravels. Moreover, the high gravels of California are far more extensive.

"The Klondike, on the other hand, is less favorably situated than Seward Peninsula, and its water supply available for mining is much less. It appears, however, that the placers of such creeks as Eldorado and Bonanza in the Klondike, averaged richer than any deposit of similar extent yet found in the peninsula. It was the exploitation of these almost fabulously rich and relatively shallow gravels that brought the Klondike gold output up with a bound, and it is their quick exhaustion that has caused an almost equally rapid decline of the annual yield. There are still extensive bodies of lower-grade gravels to mine in the Klondike, but these can be developed only by means of extensive water conduits or by dredging.

"In the comparison of the Seward Peninsula placer fields with others, it must be borne in mind that probably three-fourths of the entire production has been drawn from the region adjacent to Nome and from Ophir creek and its tributaries. Therefore, though the gold-bearing area is large, yet only a few square miles have been extensively exploited . . . and it is probable that it will be some time before the maximum yield will be attained."

MINE REPORTS.

ESPERANZA MINING CO., EL ORO, MEXICO.

The report of the Esperanza Mining Co. for the year 1907, issued on April 8, shows that this splendid property has produced to date a grand total of ₱44,797,695, from 1,136,300 tons of ore, net dry weight. During the last fiscal year the output was 155,671 metric tons (171,627 short tons), having a gross value of $3,212,666, and producing a net profit over operating expenses of $1,668,457, U. S. currency. The balance-sheets of the company show cash and assets readily realizable after providing for current liabilities of $2,047,607, out of which a final dividend for the year was paid, absorbing $506,256, and leaving a balance on hand of $1,541,357, embraced within which amount it is interesting to note, bullion valued at $393,190. Total dividend-distribution for 1907 reached the handsome sum of $3,037,500. The expenses at El Oro, including development, mining, milling, taxes, superintendence, and selling, amounted to $1,551,398, and renewals cost $30,000.

The report states, "it will be seen that they (the engineers) estimated on December 31, 1907, that there were approximately 65,485 dry metric tons (72,197 short tons) in reserve, technically 'in sight,' which should yield a profit of $225,047. Further than this, there are probabilities of profit from ore not then fully developed, and from ore which exploration is now opening up. It is also conservatively estimated that $250,000 to $300,000 profit will result from the re-treatment of the tailing dumps, after absorbing into operating charges the entire cost of re-treatment plant."

No sinking has been done in the north and south shafts during the year, the vertical depths being respectively 1440 and 990 ft. The workings aggregate 71,051 ft., of which 10,411 ft. was pushed forward within the period covered by the report. Work was concentrated wholly upon the La Esperanza y Anexas, the Sirio and Suceso properties remaining untouched.

The output of the Esperanza mine is divided into sulphide shipping ores, sulphide concentrating ores, and oxide milling ores, which latter are cyanided. The sulphide ores shipped amounted to 6163 metric tons, yielding 2.10 oz. gold and 18.57 oz. silver per short ton, having a gross value of ₱723,456, the net return from the smelter being ₱474,674. This ore by analysis showed the following composition: SiO_2, 89.62%; Fe, 2.75%; CaO, 1.45%; S, 1.83%. The concentrating ores treated reached 72,475 tons, assaying 1.04 oz. gold and 10.40 oz. silver per short ton. The gross value was ₱4,532,028, contained in 1320 dry tons of concentrate, being a concentration of 11.27 into 1. Total lost time in the mill for the entire year was only 18.73 days, a most creditable showing, being approximately 5.13%. Recovery by concentration was 33.24%, being made up of 58.58% of the gold and 30.71% of the silver. The tailing goes to the cyanide mill. This plant treated a total of 66,968 metric tons during the year, assaying 0.46 oz. gold and 7.80 oz. silver per short ton. The gross value was ₱2,181,837, out of which a bullion recovery of ₱1,820,432 was obtained, representing 67.68%, made up of 93.65% of the gold, and 66.13% of the silver. The bullion produced from the concentrator tailing showed a fineness of 55.26 in gold and 649.54 in silver, as against 125.87 and 523.85, respectively, in the bullion produced from cyaniding the oxide ores. Of the latter there were treated 77,036 metric tons, assaying 0.44 oz. gold and 2.61 oz. silver per short ton, representing a gross value of ₱1,837,555, from which a bullion-recovery was made of ₱1,632,641. The percentages of recovery were: gold, 93.82%; silver, 66.09%; total, 70.08%. It therefore appears that the mill as a whole yielded a recovery of 89.29% of the value in the crude ore. In the operation of the cyanide mill only 11.8 days were lost during the year, or 3.23%. The distribution of operating costs shows the following result, stated in terms of metric tons and Mexican currency, costs being figured on the basis of the wet tonnage, which was 163,942 tons: prospecting, ₱0.01; development, ₱1.31; ore-breaking, ₱5.08; hauling to mine bins, ₱1.35; mine to mill bins, ₱0.06; total at mill bins, ₱7.79; sulphide milling, ₱6.68; oxide milling, ₱3.73; mining, ₱8.59; grand total, including other charges, ₱14.33. The net profit per ton was ₱20.01. The average exchange with Mexico for the year was 200.79, so that the above value may be reduced to equivalents in gold by dividing by 2 without introducing an appreciable error.

It is interesting to note the condition on the 'frontier' of the mine, that is, at the faces of advance development-workings. On the San Rafael, level 5, no new orebodies have been encountered, but the known orebodies were found to be more extensive than expected. On level 6 a similar result followed development, and a new drift from cross-cut No. 24 is following a vein on the hanging-wall side of the main lode, which was found on level 7, the assay value, however, being smaller than on the lower level. On level 7 in the south section raise No. 10 was discontinued on account of the diminishing importance of the ore-streak. In the north section a cross-cut to the west has reached the boundary of the property, with unproductive result. The south drift from this cross-cut has followed the hanging-wall vein. The breast is in quartz yielding good assay values across 2 ft. On level 9 the walls are not sharply defined, and the quartz is badly mixed with included slate and porphyry, the assay value being 0.087 oz. gold per ton. The west veins have also shown little encouragement.

ALASKA UNITED GOLD, DOUGLAS ISLAND, ALASKA.

The report for the fiscal year ending December 31, 1907, is an example of complete, well classified data, with costs per ton of ore given in minute detail, figured out to the fourth place of decimals. From the profit and loss account it appears that on the total ore milled for the year, namely 213,370 tons, the operating costs, including administration and fixed charges, were $327,428, or $1.5346 per ton; construction and repairs, $2661.90, being 1.25c. per ton. On the Ready Bullion property, the total costs were $1.54 per ton, and the total yield was $1.69, leaving a net return of 15c. per ton. The average results from the operation of this property since 1898 have been a recovery of $1.89 per ton, against a cost of $1.64, on a total of 1,841,079 tons treated to date, giving an average net profit of 25c. per ton.

Active exploration and development has been going forward amounting to a total of 2372 ft. advance for the year. The ore reserves in the Ready Bullion mine are estimated at 1,378,651, and in the 700-ft. claim at 355,082 tons. The assay values, deduced from 1820 and 526 samples respectively are $2.14 and $2.46 per ton. The gross value of ore crushed in 1907 was $1.8352 per ton, and the loss in tailing was 18.75c. The mill, of 120 stamps, crushed at the rate of 5.75 tons per day per stamp, at a cost of 35.71c. per ton. The recovery from free gold was $1.0505, and from concentrate 63.84c. per ton. The mill was operated 309 days in the year, the loss being therefore approximately 15% of possible time. Further analysis of the milling record shows the following: ounces quicksilver fed to batteries per ton of ore, 0.1301; to plates, 0.0093; to vanners, 0.0040; losses, 0.0346, being a total of 0.1780 oz. per ton. The quicksilver lost was 34.88% of that used. The supplies consumed were 519 shoes, 250 dies, 20 cams, 9 cam shafts, 13 tappets, 5 mortars, and 10 vanner belts. Stems broken and replaced numbered 450. The year's work showed that 1 lb. of chrome steel in the shoes crushed 2.39 tons of ore, and 1 lb. of iron in the dies, which were cast in the Treadwell foundry, crushed 6.09 tons at a total cost for iron and steel of 2.97c. per ton of ore. The distribution of milling costs per ton of ore was: labor, 10.50c.; merchandise, 4.14c.; iron and steel, 3.52c.; foundry, 1.33c.; steam power, 16.4c.; total, 35.89c. At the mine the total costs were 99.94c. per ton, distributed as follows: labor, 52.14c.; merchandise, 6.88c.; iron, 0.09c.; steel, 0.32c.; miscellaneous iron and steel supplies, 1.7c.; foundry, 0.17c.; powder, 15.24c.; steam power, 24.61c.; total, $1.0115, which is reduced by sale of scrap iron to the figure first given.

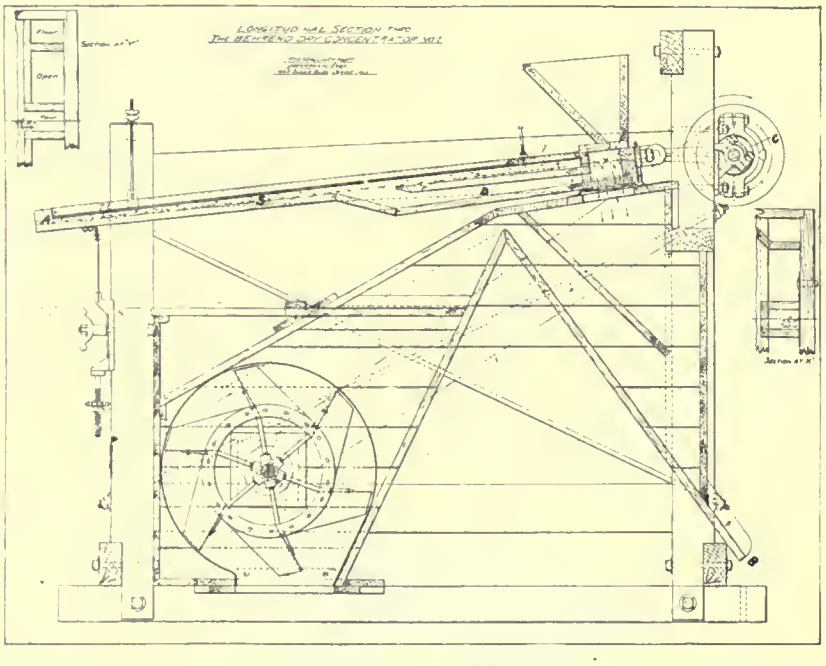
The great increase in the cost of coal, which was $9.12 per ton, as against $5.39 the previous year, has led to the installation of oil-burning equipment, which will materially reduce operating costs in future.

NEW CONCENTRATOR.

The Behrend Dry Concentrator Co. has established offices at 10 Wall St. and at 61 Pearl St., New York. This company has placed on exhibition one of its concentrators. Tests have been run daily on ore received from many parts of this country. The following description of the concentrator will prove of interest.

By referring to the sectional drawing of the machine it will be seen that the air is taken in at A, and is carried over the table S (arrows showing direction), the tailing discharging at B. The table is under rapid vibration by the eccentric C. The dressing-plate covers the table, which in combination with the same constitutes an air-flue; the plate being movable in a perpendicular line so as to be raised or lowered, creating a variable air force or current according to the specific gravity of the materials under treatment and insuring discharge at any degree of concentration desired. The volume of air and ore-feed are under complete control.

The new machine operates on the principle of air-exhaust. the current created by operation of the fan enters the lower end between the table and top movable dressing-plate. Where the concentrate is discharged the air force can be perfectly regulated so as to carry the lighter gangue into the base of the machine onto baffle-boards, and when sufficient weight has accumulated a flexible outlet-valve opens and discharges the tailing. The table being under rapid vibration, beds the heavy material as it moves down in a direction opposed to the air current; the lighter gangue, coming to the surface, is carried off, and the concentrate is discharged as before described. The dust from raw ore undergoing dressing is carried with the exhaust air into ducts and outside of the building into chambers, if desired, or into the open air at a remote point.



JOINT FOR PIPE CONNECTIONS.

The forged steel bolted joint perfected lately by the American Spiral Pipe Works, of Chicago, is claimed to be the most perfect steel pipe-connection or bolted joint ever devised for hydraulic purposes. It is made entirely of steel, and is, therefore, unbreakable. in transport, handling, or use. It consists of two forged steel flanges, with necessary bolts, and a centre sleeve or body recessed at both ends to allow for the insertion of beveled edge rubber, used as packing.

Pipe connections, using this joint, are made in the following manner: Flanges are first slipped over the ends of both pipes to be connected, and the centre sleeve or body is driven over one end of the pipe until it strikes an elevation on the inside of the sleeve. Then the other pipe is taken up and forced into the other end of the sleeve. Beveled strips of rubber, of ample dimensions, cut to the exact length to conform to the circumference of the pipe, are next placed on the pipe and pushed into the recess in the sleeve, or the space between the pipe and the centre body. The flanges are next brought toward the body and bolts put in and drawn up evenly around the pipe. The hubs of the flanges engage the rubber, causing it to expand, making the joint absolutely tight under pressures up to about 250 or 300 pounds.

Besides its many other advantages, this bolted joint will allow slight deflections to be made in the pipe, so as to conform to changes in grade-lines. They are made in sizes from 6 inches up to 34, inclusive.

PUBLICATIONS RECEIVED.

The following re-prints by J. Volney Lewis have been received: 'Geological Survey of New Jersey,' Part III of Annual Report for 1906; 'Bulletin of the Geological Society of America' on the Structure and Correlation of Newark Trap-rocks of New Jersey; and 'Copper Deposits of the New Jersey Triassic,' from Economic Geology.

COMMERCIAL PARAGRAPHS.

THE MOORE FILTER CO. moved their offices May 1 to the Broadway-Maiden Lane Bdg., 170 Broadway, New York City.

THE MEXICAN MINES PROSPECTS DEVELOPMENT CO. has moved its Mexico City offices to the Bancaria Bdg., 5 de Mayo 32.

THE BRETHERTON METALLURGICAL CO. has opened an office at 532 Commercial St., San Francisco, as consulting engineers, assayers, and chemists.

ROBERT W. HUNT & CO. have established an analytical chemical laboratory in connection with their St. Louis office, at 1445 Syndicate Trust Building.

ALLIS-CHALMERS CO.'S district office, formerly in the Atlas Bdg., has been removed to the Phillips Bdg., 599 Mission St., San Francisco. H. D. Scribner is manager.

THE JOHN A. TAYLOR MACHINERY CO. announces the International Machinery & Engineering Co. of Mexico City as agent for its full line of goods in that territory.

THE HUG WATER WHEEL CO., of Denver, Colorado, recently sold one 900-hp. direct connected water-wheel unit to the United Hydro-Electric Co. at Georgetown, Colo.; one 750-hp. direct connected water-wheel to the Continental M. & M. Co., Idaho Springs, Colorado; one 36-in. wheel to Clearwater Gold & Copper M. Co., Iron Mountain, Montana, and one 48-in. wheel to D. M. Reedy, Boulder, Colorado.

BOOKS RECEIVED.

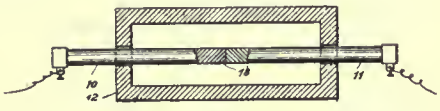
'Earthwork Computations.' By C. W. Crockett. 114 pp. $1.50. John Wiley & Sons. For sale by the MINING AND SCIENTIFIC PRESS. This book gives a number of rules by which the terms necessary for the numerical computations of volumes may be written directly from the notes. One chapter explains the use of the author's slide-rule for the computation of volumes.

'The Electric Furnace.' By Alfred Stansfield. Hill Publishing Co. 211 pp. Price $2. For sale by the MINING AND SCIENTIFIC PRESS. The book gives a full account of the present knowledge of electric smelting practice. The general principles of the subject are clearly stated, and much valuable information can be found in this little volume. The difficulty of securing accurate data, owing to the secrecy maintained in most works, prevents the publication of many definite figures, but the fundamental principles are excellently described.

MINING AND METALLURGICAL PATENTS.

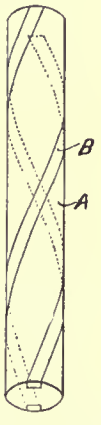
Specially Reported for the MINING AND SCIENTIFIC PRESS.

THERMO-ELECTRIC COUPLE.—No. 885,430. William H. Bristol, New York, New York.



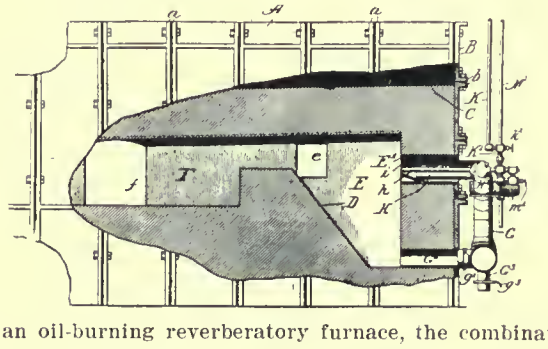
A thermo-electric couple, the two elements which consist of graphite.

STAMP-MILL SHAFTING.—No. 885,259. Frank S. Kirkland, Milwaukee, Wisconsin.



A metallic shaft having an exterior groove therein and a strip of copper electrically welded in such groove, for the purpose specified.

OIL-BURNING REVERBERATORY FURNACE.—No. 886,050. George Fraser, Topeka, Kansas.



In an oil-burning reverberatory furnace, the combination with an initial chamber, of a working chamber, said chambers having a continuous dome, a rearwardly inclined bridge wall intermediate of said chambers, a burner located in the same horizontal plane as the top of the bridge wall and extending in concentric alignment with an opening in the furnace front, said opening being adjacent the under surface of the dome of the initial chamber, an air supply conduit communicating with said burner, an oil supply conduit communicating with said burner, and means for regulating the supply of oil and air to said burner.

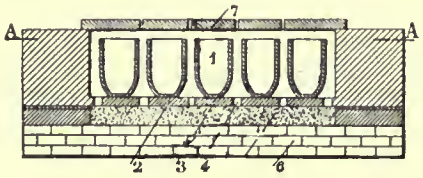
METALLURGICAL TREATMENT OF SULPHUROUS ORES BY THE PRECIPITATION PROCESS.—No. 875,579. Antoine H. Imbert, Grand-Montrouge, France.

The process of reducing metallic sulphides which consists in heating the sulphide in the presence of an oxide and a sulphide of such a character that they will form a dissolvent for the said metallic sulphide with a metal having a greater affinity for sulphur than the metal of the sulphide being reduced.

EXCAVATOR-BUCKET.—No. 885,049. Alpheus E. Holcomb, Chicago, Illinois.

An excavator-bucket having a bottom composed of transverse slats or bars mounted on flexible members supported at their ends, substantially as described.

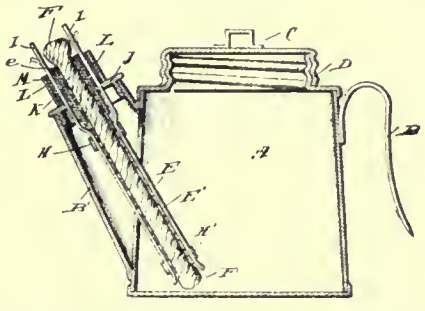
ELECTRIC FURNACE.—No. 885,745. Paul Girod, Ugine, France.



In an electric furnace, the combination, with a receptacle forming a chamber arranged to receive a plurality of objects to be heated, of a mass of resistance material arranged in layers in contact with the sides, ends, and bottom of said receptacle, and a plurality of pole pieces of opposite polarity at each end of the receptacle.

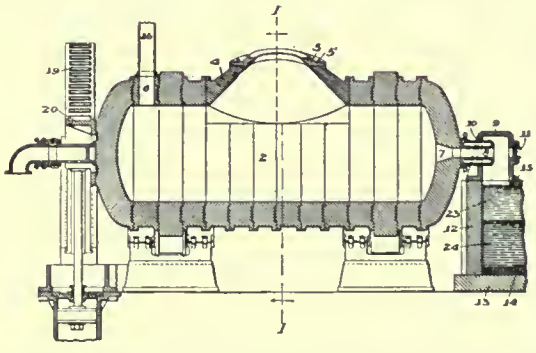
In an electric furnace, the combination, with a receptacle forming a chamber arranged to receive a plurality of objects to be heated, and provided with end extensions, of insulating masonry inclosing said receptacle and arranged to support said extensions, a mass of resistance material between the receptacle and the masonry pole pieces extending through the masonry and arranged to conduct current to the resistance material.

MINER'S LAMP.—No. 886,204. Ralph L. Graves, Sumter, Oregon.



In a miner's lamp, the combination with the spout thereof, of a wick tube container adjustably held in said spout, said container comprising a series of wires held in tubular arrangement, the upper portion of said container being of greater diameter than the lower portion thereof, of a wick collar having a slot in one side and rigidly secured to said spout and projecting beyond the same, within the upper portion of the container, a sleeve surrounding said collar, and provided with slots, and an expansible foraminous wick tube horizontally flanged at its outer end and snugly held in said container and adapted to be longitudinally adjustable in the container by a candlestick pin inserted through the aforesaid slots and to be removed from the outside by means of the aforesaid flange.

SMELTING CONVERTER AND FOREHEARTH.—No. 886,030. Ralph Baggaley, Pittsburg, Pennsylvania.



Apparatus for recovering mineral values from ores which consists in the combination of a smelting converter provided with an ore inlet at one end and with a water-jacketed slag and matte overflow-spout at the other end with a separating vessel and having a covered drop-tube between the overflow-spout and the separating vessel provided with means whereby access may be had to the overflow-spout for examination and rodding when occasion requires substantially as described.

Editorial.

WE NOTE that our Salt Lake correspondent states that the Ogden smelter "was run for several months last year, proving to be a failure financially but a success metallurgically." This is too much like the surgical operation which was a perfect success, but the patient died. We are glad to believe that the antiseptic treatment of anti-trust enthusiasm will restore the Ogden smelter to a position of usefulness, both metallurgically and financially.

ANNUAL REPORTS of mining companies often contain information of value to mining engineers and mine managers, so we publish a synopsis of one or two such reports in each issue. This week the operations of the North Star mine come under review. No mine has done more to sustain the reputation of California as a mining region; in fact, we may say that the North Star and its neighbor, the Empire, are among the best mines in America. The Empire has been worked without interruption for 55 years and is now 3500 feet deep on an incline of 27°, giving a vertical depth of 1500 feet, while the North Star, which was started in 1850, is 5000 feet deep on an incline of 24°, or 1800 feet vertically. Both mines are producing high-grade gold ore and earning handsome profits, with an outlook for decades of successful operation from orebodies actually explored and proved.

WE NOTE with pleasure that Mr. Arthur L. Walker has been appointed professor of metallurgy in the School of Mines of Columbia University. He will serve as administrative head of the department and take personal direction of the instruction in non-ferrous metallurgy and metallurgical design, thus giving the senior professor, Mr. Henry M. Howe, additional time for research. Mr. Walker is himself a graduate of the Columbia School of Mines of the class of 1883; his first important appointment was as superintendent of the Old Dominion mine at Globe, Arizona; later he changed from mining to metallurgy and was in charge of the Baltimore smelter, whence he was promoted to the management of the Perth Amboy smelter, where he made many valuable improvements in the methods of copper refining. In 1906 he became a member of the executive committee of the American Smelting & Refining Company, and designed the proposed copper smelter for San Bruno, near San Francisco. In March of this year he resigned from the service of the Guggenheims and commenced private practice as a consulting metallurgist. Thus, by training and by experience, Mr. Walker is well fitted to be an efficient teacher. Moreover, by reason of his previous professional success, he is not financially de-

pendent upon his salary as professor. This is the kind of man needed to give life and force to the teaching obtainable at a school of mines, and we congratulate Columbia University on her new professor as much as we congratulate her alumnus on the opportunity to do good service for his alma mater.

IN the London *Mining Journal* of April 25 there appears an article on the world's production of gold by Mr. Waldemar Lindgren. We are informed by him that it is a short-hand report of a paper read at Joplin last November, and as now printed it is full of errors. Apparently it was copied from the records of the American Mining Congress.

THE NEW YORK papers have had a good deal to say in regard to the confession of Mr. William Travers Jerome, the District Attorney, that he was shaking dice with the sons of Thomas F. Ryan at the time Mr. Delphin M. Delmas was summing up for the defence in the Thaw trial. By the way, what memories of belligerent politics, of Pittsburg debauchery, New York predatory finance, and Californian rhetorical confectionery are revived by the names just mentioned; it seems like awakening the gibbering ghosts of a bad dream. To return to Mr. Jerome and his dice: we note that the information was elicited in the course of a hearing on charges of dereliction of duty brought against the celebrated District Attorney by a committee of shareholders in the Metropolitan street railways. We regret that a man who has stood in the front rank of reformers should apparently have been influenced by his social environment and have given cause for doubting the sincerity of his purpose. Jerome has done so much splendid work as an outspoken honest politician that we hope the enquiry will end in his complete vindication. But as to the throwing of dice: this is a pastime not unknown in San Francisco. It is a curious survival of frontier barbarism. Nothing that educated men do is more opposed to what is termed good taste, that is, a cultivated appreciation of what is befitting. A man asks a friend to take a drink, the friend insists that he act as host, they agree to throw dice, and the loser pays; in other words, the successful throw of the dice is accepted as an opportunity for evading the act of courtesy for the privilege of which the two have been striving good-naturedly. A man accepts the arbitrament of chance as a permission to impose upon his friend the payment which he was claiming as an honor a few minutes earlier. It is a silly custom and, apart from the introduction of a gambling device, transgresses the most elementary principle of social courtesy. We are sorry Mr. Jerome was caught in the act.

GEOLOGISTS and miners will enjoy the article by Mr. James F. Kemp, professor of geology in Columbia University, for, whether the waters that form ore deposits be magmatic or meteoric, it is evident that those of which the Professor partakes are sparkling, for how otherwise could the result of his studies be so refreshing? The Professor, who surveys the barysphere from the heights of Morningside, has given us something more stimulating than mere waters, whether those from above the earth or those from under, and he has injected some of the kindly humor that makes the graduates from the Columbia School of Mines look favorably even on paleontology as taught on the banks of the Hudson. We hope that some of our mining geologists will add further to the usefulness of Mr. Kemp's article by contributing to the discussion of the subject, surely one of the most vital to the understanding of the origin and distribution of ore deposits. We shall not offer comment at this time, hoping to hear from our readers first. But we venture to express agreement with the author's humorous reference to the Government geologist who remembered the names of those with whom he disagreed in regard to a scientific question, but forgot the names of those whose ideas agreed with or antedated his own. We confess to being mean enough to chuckle as we read Mr. Kemp's remark, for we have been aware of this little frailty in several writers of Survey publications. In the course of their work they examine mining districts previously investigated, under difficulties, by mining engineers; the pioneer work is apt to be faulty, but it is likely to have ascertained the main features of ore distribution and possibly of rock structure; when the Government geologist (for whose work the engineer as a tax-payer has contributed) arrives on the scene, he utilizes all the available information, and writes a monumental report; in that report he refers to the writings of the non-official geologist only to emphasize points of minor disagreement, making scant, if any, acknowledgement of the help afforded by the same writings. Such things have happened, and the frank mention of them is more likely to prevent friction in the future than to cause trouble in the present.

The Greatest Gold Mine.

OUR LONDON correspondent makes the claim for the Waihi mine, in New Zealand, that it is the greatest gold mine in the world. During the last three years the production has been increased from £733,561 in 1905 to £888,585 in 1907, permitting of an increase in dividends from £346,554 to £442,599, the ore crushed increasing at the same time from 298,531 to 356,974 tons per annum. The yield remains unchanged at 49 shillings per ton, while the cost has been diminished from 21 to 20 shillings. Meantime the ore reserves have been augmented from 938,334 tons at the end of 1905 to 1,299,947 at the end of 1907. Thus there is assurance of a gross production of $4,500,000 per annum and dividends of $2,500,000 for a term of 3½ years. The Robinson mine in the Transvaal is ahead of the Waihi in the amount of its reserves, for it has no less than 4,000,000 tons assured, enough to maintain the present rate of production for 8 years. The production, at the present time, is $6,000,000 per annum, yielding dividends of $3,250,000. In amount of dividends both mines have increased lately, but the Robinson is still ahead. The essential difference between these two great mines lies in the fact that the Robinson has

been explored and developed to its full extent, for in depth the lode passes into a neighboring deep-level property, which incidentally has demonstrated the persistence of the orebody. The Robinson has no apex rights, and is unable to follow its ore beyond the vertical plane of its side-line, while the Waihi has ample room, and can pursue its ore to the maximum depth permitted by human skill. The Robinson has a magnificent but limited future, the Waihi has splendid and, as yet, unlimited possibilities. One is waning, the other is waxing. If the Waihi does not soon exhibit those signs of impoverishment that are inevitable sooner or later in all gold veins, the Robinson will have to take second place, for greatness in a gold mine is measured by two factors, namely, present net yield and assured future productiveness.

Preservation of Natural Resources.

NO ACT of Mr. Roosevelt evinces the intense and real patriotism of his character better than the summons to the Governors of the States to a conference intended to devise ways and means for stopping the waste of natural resources. The conference has proved a notable success. An astute politician, the President can at times display the qualities of the highest statesmanship and he does it in such a forceful sensible manner as to arouse the keen enthusiasm of the American people. Nothing he has done during his double term as President is fraught with such far reaching benefit to the country as this masterful effort to awaken the intelligence and conscience of the nation to the rapid destruction of natural resources. The average man has been inclined to ask: "What has posterity done for me?" And having relieved himself of this Hibernian query, "the heir of all the ages" proceeds to enjoy himself. Thus the intensely unsocial selfish spirit of modern industry has been permitted to despoil a continent in the fierce haste to gather the riches of ore, timber, water, and soil, until suddenly the conscience of the people has been alarmed and the intelligence of thoughtful men has been awakened to a realization of the fact that the inheritance of their children is being devastated. The destruction of timber to make pulp for manufacturing paper is one that impresses us most, for the purpose of it is so largely useless. A yellow journal needs 20 acres of wood to make the paper for one of its Sunday editions! It costs 2080 acres of woodland per annum to print one newspaper! And for what are the forests destroyed, the mountains stripped of their verdure, so as to cause alternate flood and water famine; for what is the land deforested? For a mass of misinformation, for the degrading rubbish of journalism, for vulgar pages of colored print, for all that is opposed to enlightenment and education. It is a hideous waste indeed, for it is the sacrifice of something beautiful and useful to produce something altogether unlovely and vicious. But the timber question is only one of many; there is that of waterpower, coal, iron ore, soil, every one of the basic resources on which our complex civilization is built. They are passing into the hands of the predatory few, for distribution at rising prices to the luxurious many; they are being squandered in the interest of a handful of men, instead of being so conserved, so garnered, and so utilized as to contribute to the well-being of a maximum number, not only of this generation but of those to follow. Never was there a nobler call to real patriotism—not to pride of country nor blatant jingoism, but the willingness to do something in the service of America as a whole, to serve the Americea not of today alone but of the days that are to come. Is this richly endowed continent to become as bare as China, as barren as Assyria; are famine and flood to stalk over the once verdant mountains and the formerly fertile plains of America as over other lands where deforestation has been carried to a finish? Shall the water we drink and the power that runs the machinery of a vast industrial complex pass into the hands of a few exploiters? It is not too late, but it soon will be too late, to take such action as will check the destruction and stop the spoliation. Mr. Roosevelt has done a splendid service.

Philippine Mining Code.

AN association has just been formed in the important Baguio district in the Province of Benguet, Philippine Islands, for the promotion of the mineral industry and a closer co-operation among all the mining districts of the Islands. The association has displayed commendable energy and an appreciation of opportunity in the beginning by appointing a committee which has undertaken the serious task of drafting a mining code, based upon the laws of the United States and Canada, to supersede the defective regulations now in force. The Philippine Commission has accepted the revised code in principle, subject to harmonization with the laws of the United States. We note with interest the adoption of the square mining claim, with rights restricted to side-lines. This is in conformity with world-wide practice, the so-called 'law of the apex,' with its extra-lateral uncertainties, being an American invention. Whatever may be said in its favor as a system to which the United States is committed, the fact remains that when the rights of proprietorship are limited within vertical planes the owner and his neighbor know what pertaineth unto each. That is something at least which appeals favorably to the general mass of mankind, for most men have a leaning toward absolutism, fixedness, recognizable metes and bounds in all three dimensions, however false to the teachings of philosophy conclusiveness may be, and however unproductive of contributory fees to the legal fraternity. To unsettle our mining laws by a change from the extra-lateral right after all these years would be to work disaster to great industries, but to impose our system upon the Philippines when the leading authorities at home are not in agreement over the essential desirability of the law of the apex, while the rest of the world has gotten on well with the old-fashioned tenure that has stood the test of centuries, would seem to be an act of folly. Evidently the people of the Philippines prefer to abide by the evils that they know, than fly to those they know not of.

Personal.

F. W. Bradley is at Tacoma.

Robert Schorr is at Bielitz, Austria.

Harold Braly has returned to Skidoo, Inyo county, California.

W. R. Crosby has gone to Virginia City, Nevada, for a week's stay.

Henry F. Lefevre passed through San Francisco on his way to Mexico.

Frank H. Probert has moved his offices to the Central Bdg., Los Angeles.

G. L. Guthrie has returned from Costa Rica to his home in Atchison, Kansas.

S. J. Kidder of the Desert mill, at Millers, Nevada, was in San Francisco last week.

Chas. E. Uren was in San Francisco last week, on his way to Shawmut, California.

Edgar Newhouse, of the A. S. & R. Co., was here from New York. He has gone to Tacoma.

C. H. Munro is going to Nome to take charge of operations for the Wild Goose Mining Company.

Arthur L. Walker has been appointed professor of nonferrous metallurgy in Columbia University.

W. H. Lanagan leaves for Nome, Alaska, at the end of this month, and will probably remain in Alaska through the winter.

G. H. Clevenger sailed from San Francisco on May 22 for Salvador, to assume charge of a cyanide annex at the Devisadero mine.

J. T. Stevens, superintendent and one of the owners of the Harris mine, at Washoe, Nevada, spent last week in San Francisco.

C. S. Herzig, for the past five years with Bewick, Moreing & Co., has opened an office as consulting engineer at 62 London Wall, London.

E. R. Buckley, formerly State Geologist of Missouri, has resigned to accept the position of mining geologist to the Federal Lead Company.

Arthur S. Eakle, professor of mineralogy in the University of California, has taken a holiday and is now at Washington Grove, in Maryland.

J. E. Spurr and G. H. Garrey, of the firm of Spurr & Cox, are making a geological survey of the property of the Inde Gold Mining Co., in Durango, Mexico.

H. M. Adkinson has resigned as superintendent of the New England Mining Co., at Bingham, Utah, to take a position with A. E. Reynolds in Colorado.

Almon D. Hodges, Jr., editor of the Mining and Scientific Press in 1869 and for three years thereafter, was in San Francisco for a few days on a visit from Boston.

S. F. Shaw, superintendent of the Granadeña Mining Co. at Santa Barbara, Chihuahua, was in San Francisco, and has gone to visit mines in Oregon and Washington.

D. A. Lyon arrived in San Francisco on May 16, from Heroult, Shasta county, California, where he is building an improved electric furnace for the reduction of iron ores.

OBITUARY.

Arthur Koppel, senior officer of The Arthur Koppel Company, died suddenly of heart failure at Berlin on May 13. His death was entirely unexpected, as he was in active charge of his enormous affairs up to the time of death. As an engineer and inventor of economic transportation systems he was well known all over the civilized world. From a very small beginning 35 years ago he had personally built a diversified and progressive industrial establishment, and in the mining fields of Europe, Africa, South America, Mexico, and Australia his enterprise made itself felt, as much in pushing his business as in the kindly interest taken in the welfare of his employees.

L. Vogelstein & Co., New York, give the following figures of German consumption of foreign copper for the period January to March, 1908:

	Tons.
Imports of copper	44,914
Exports of copper	2,084
Consumption of copper	42,830

as compared with consumption during the same period in 1907 of 24,393 tons. Of the above quantity 41,999 tons were imported from the United States.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Fifty feet of ore and altered matter has been cut in a drift which has been driven to the northeast at the 235-ft. level of shaft No. 3 in the Santa Rosa mine, 18 miles south of Douglas. This shaft is now 300 ft. deep.——Joe Bishop has secured a two years' lease on the Bonanza property, in the State of Maine district, and started work. He will sink a new shaft.

GILA COUNTY.

The Old Dominion will probably sink a new shaft at the Continental mine. Two cars of horses and two cars of wagons were recently shipped from this mine to Dalton, Cal., to be used in hauling ore.——The Stonewall mine, 16 miles northeast of Globe, has been re-opened and will be developed by the McMillen Stonewall M. Co. This mine was a great producer twenty-five years ago, and at that time no ore which contained less than 50% of silver was worked. The new company will sink a three-compartment shaft at

Map of Arizona.

a point where the vein is known to be 100 ft. wide.——Development in the Gem shaft of the Globe Con.'s property showed that the Future copper vein is a heavily mineralized orebody 65 ft. wide.——It is reported that development work will begin within 60 days on the holdings of the London Mountain Copper Co. in the Banner district. The Saddle Mountain Copper Co., which owns the adjoining property, is getting ready to operate its 150-ton smelting plant. The grading for a railroad track from Winkelman to the Saddle Mountain camp is completed, and it is claimed that the Southern Pacific will lay track when needed by the mining company.——According to returns to the Assessor, the production of Gila county for 1907 amounted to 35,009,984 lb. copper, 2662 oz. gold, and 91,303 oz. silver. The copper production is an increase of 21% over that of 1906, the gold is an increase of 19%, and the silver a decrease of 5 per cent.

SANTA CRUZ COUNTY.

(Special Correspondence).—The shaft at the Morning Glory mine, in the Harshaw district, is now down 100 ft. and shows a vein of copper 6 ft. wide.——The drifts at the Leek-McDonald mine have been run along the vein at the 200-ft. level for a distance of about 200 ft. and cross-cutting will now be commenced to ascertain the width of the vein at that depth. The ore is a sulphide of copper.——A hoist is being put in place at the shaft of the National Con. M. Co., in the Patagonia mountains. The shaft is down 175 ft. and will be sunk to the 200 when the hoist is in place. Shipping ore is being stoped at the 100-ft. level.——A 650-ft. adit is being driven into the hill to cut the vein at the Four Metals mine, in the Patagonia mountains. It is in 400 ft. and will have a depth of 600 ft. under the capping when completed. A number of new buildings are being erected at the camp.

Patagonia, May 19.

YAVAPAI COUNTY.

(Special Correspondence).—The Juanita Co. expects to install an air-compressor and hoist at its property, 18 miles south of Prescott. Development has been carried on for two years, disclosing both gold quartz and copper-iron sulphides. ——The Poland M. Co., in Big Bug canyon, is milling 50 tons of ore per day and shipping the concentrate to the Needles smelter. One of the features of this mine is the 8000-ft. tunnel that cuts through the mountain ridge from the mill level at Poland to the Lynx creek side at Walker. This tunnel is not only used for transporting ore to the mill, but also for hauling merchandise from the railroad at Poland, to Walker.——The Arizona Power Co. is building a power plant on Fossil creek near its junction with the Rio Verde. The dam is now under construction and it is expected that by the end of this year two generators will be furnishing power to the mines of the county.——G. P. Henderson will put a small pumping plant in the 100-ft. shaft of his property 15 miles south of Kirkland.——The Hale Co. is developing its property 15 miles northeast of Wickenburg, and has installed a gasoline hoist. The shaft is 470 ft. deep, in which ore containing both gold and copper in iron sulphide has been discovered.——The Goddard Co., which owns six claims near Wickenburg, will install a hoist of greater capacity and sink the shaft 200 ft. deeper.—— A small mill for concentrating copper ore has just been completed at the Monarch mine, nine miles from Wickenburg.

Wickenburg, May 18.

CALIFORNIA.

BUTTE COUNTY.

As a result of an accident to the pump at the Stiefer mine, near Oroville, the workings are again flooded. The water was down to within two feet of the point where the motors and other machinery could be rescued when the accident happened. A new pump will be secured and work resumed.

CALAVERAS COUNTY.

Operations will be resumed at once on the Chapman gravel mine on the outskirts of San Andreas. A new shaft will be sunk.——Litigation over the famous Morgan mine, near Angels, has been amicably settled and preparations are being made to open the property, which in the early days yielded millions to its owners. The Irvine heirs received a large sum (the exact amount is not stated) from Mrs. Oelrichs and Mrs. Vanderbilt, for which they in turn have deeded all their interest to the millionaire owners.

NEVADA COUNTY.

(Special Correspondence).—A 16-in. vein of rich ore has been struck in the north drift on the 200 level in the Kenosha. Several specimens of bonanza ore have been taken out. A drift is being driven to cut the Riley shoot. The shaft is going down steadily.—Williams, Ryan and Whiting are preparing to ship a carload of ore from their property to the Selby smelter for a test run.——The fifth raise at the Jenny Lind has cut the channel and exposed large quantities of rich gravel. The aerial tramway has been completed and the mill will start soon. The mine will be in full blast within three weeks.——It is announced that the Sazerac mine will soon be re-opened.——It is reported that the Alta mine will be worked soon.——The adit at the Leduc is in 20 ft., good progress being made. It is expected the lode will be intersected within 250 ft.——Rich ore continues to

come from the drift in the 500 level of the Idaho-Maryland. A winze is going down from the 500 to the 600 level. The drift on the 700 level is being cleaned up. The working force has been augmented.——Good ore is coming from the 400 level of the Central Consolidated. Good quartz has been taken from the croppings, about a mile from the mill.——It is reported that the Brunswick Co. is endeavoring to acquire additional territory for the sinking of a new shaft.——The St. Goddard Co., operating the Delhi mine, has declared a dividend of 5c. per share, a total of $5000. The mine is situated on Columbia hill. It is well equipped and is expected to pay several dividends this year.——R. B. Day, of Alaska, and eastern associates have secured a bond on the Arctic group of mines in the Washington district. The amount involved ranges from $75,000 to $100,000. The bonders will install considerable machinery, including a 20-stamp mill, air-compressor, and hydraulic power-plant. Five veins, running from 2 to 25 ft. wide, traverse the property. Values run from $10 to $1000 per ton in gold.——Development work is going on at the Mountain View.——The Ethel M. Co. is planning to drive a long adit and sink a shaft on its property. Work is under way at several points and good ore is being developed.——A 4-ft. vein of high-grade ore has been struck in the Red Ledge claim, near Washington. A 6-in. streak assaying from $2000 to $30,000 per ton runs through the vein. The find has aroused great interest and several claims have been staked around the scene of the discovery.——Several strikes of importance are reported from the Cherokee section.——The mining industry around Grass Valley is displaying greater activity at the present time than has been manifested for several years.

Grass Valley, May 18.

PLACER COUNTY.

Four men are working at the Valley View mine, cleaning out the old Taylor shaft. A new hoist and head-frame have been put up. The pumps are going night and day, and the re-timbering is being done as fast as the water is lowered. As soon as the shaft, which is 180 ft. deep, has been pumped out, driving and cross-cutting will begin, and a large force of men be put to work. E. Cartwright is superintendent. ——Work will start soon at the Hibbe mine, 12 miles northeast of Lincoln. The mine has been bonded to an eastern company, which, it is reported, will put in new machinery. ——W. S. Fletcher is putting up a 2-stamp mill at his Home Ticket property. He will use electric power.——Lee McCoy is to start a new adit at the lower level on his Vier claim on Georgia hill.——The dredge at the Cash Rock has opened a pit 15 ft. deep, and at this rate the suction pipe should reach bedrock in a short time. The suction pipe is protected by a triangular shield, which serves as a guard to the divers. Boulders as large as 8 in. diam. are drawn through the pipe. The big boulders are raised with grappling hooks attached by the diver, and dumped to the rear of the boat. The sand and smaller boulders are sucked up and dropped upon grizzlies, through which the sand drops into boxes, which are arranged in tiers and move around in nearly a circle so as to give time and space for catching the gold. The boulders pass on over the grizzlies to an endless belt, which carries them to the stern of the boat, where they are dumped into the river. Two divers are employed. They are dressed in regular diving suits and work six hours. Several pieces of heavy river-washed gold have been found in the boxes.

SISKIYOU COUNTY.

Construction has been started on the hull of the dredge which the Scott River Dredging Co. is building on Scott river, near Callahan. The machinery is being hauled from Yreka.——The Oregon placer mine, below Happy Camp, has closed down on account of the suicide of Charles Coster, who was the principal stockholder.——The Nash mine, on Coffee creek, has been leased to R. G. Abrams, who will work it on a large scale.——A new elevator has been put in at the Grider mine, in Seiad valley, and actual mining started. The new elevator has a 16-in. pipe with a 14-in. throat.—— The Klondike mine, on Ash creek, has ordered new machinery to handle 50 tons per day, which will be operated by electric power from the plant of the Siskiyou Power Co. ——Word & Brown have struck the vein in the lower adit of their copper mine on Indian creek.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—The Mint group of claims on Kelso Mtn. are again undergoing development. It has been practically assured that an electrically driven plant will be purchased. The Mint adit is now in about 300 ft. and will be continued to the intersection with the cross veins. Within 600 ft. the entire group will be reached, at which point drifts will be driven.——The Smuggler, on Brown Mtn., is the scene of one of the latest strikes. In running the west drift from the fourth level a streak of solid smelting ore has been exposed that measures from 16 to 20 in. wide. The ore assays as high as 220 oz. silver per ton, and 30% lead. Lessees on the third level of this property have been maintaining steady shipments of ore for several months, the average value of the product being $100 per ton in silver and lead.——Since the night shift was put on at the American Sisters mine on Columbian Mtn. the output of smelting ore has been more than doubled. Drifts are being driven on the 275-ft. level, and a streak of ore is followed that is from 18 in. to 2 ft. wide. The drift is now 700 ft. long and the orebody is showing for 300 ft. Stoping is under way, and from recent mill runs average returns of $160 per ton in silver and lead have been received. The mill, of 50 tons capacity, is being run night and day, and shipments are made semi-weekly.——At the Sidney tunnel, Carlson & Co., operating under lease, made a shipment of 50 tons of second-class ore last week that brought a net return of $40 per ton in silver and lead. These men are carrying a stope upon a body of ore that is from 4 in. to 3 ft. wide, a portion of which mills as high as $80 per ton. Killin & Co., leasing to the east, are sending out from 20 to 25 tons of ore monthly that assays 2 oz. gold, 35 oz. silver, and 50% lead. The compressor plant at the tunnel is again in operation and machine drills are in use.——An 18-in. streak of high-grade ore has been encountered in the Pilsen vein, intersected 275 ft. from the entrance of the Pilsen adit. Driving is now in progress, and an average tonnage of ore is being extracted. Assays show 60% lead, 35 oz. silver, and ½ oz. gold per ton. Shipments are to be started in a few days over the Argentine Central.——Wood & Co., leasing on the fourteenth level of the Terrible, are breaking a heavy tonnage of high-grade ore. Mill tests have given a return of $70 per ton in silver and lead. A big body of mill dirt is being followed in the stope, the product being sent to the company mill for concentration.——Work has been resumed on the Raymond adit, after a close-down of four weeks. Driving is in progress upon the Paris vein, cut 800 ft. from the adit entrance, while a streak of $40 silver-lead ore is being followed that is from 4 to 8 in. wide. Stoping will be started soon.——Work has been resumed on the Snowdrift group of claims on Republican Mtn. The Kalamazoo adit is being advanced to intersect the Snowdrift vein, and the objective will be reached within 150 ft. This property has the distinction of having produced the highest-grade silver ore ever mined in the Georgetown district. In 100-ton lots, returns running as high as 15,000 oz. silver were received from marketing the surface product. The deepest workings are down 240 ft., but through the Kalamazoo adit an increased depth of 350 ft. will be secured. ——An electric trolley system will shortly be installed at the Capital adit being driven by the Capital M. & T. Co. Such a heavy tonnage of ore is being broken from the stopes on the Aetna vein that some system must be devised for the transportation of the product. In the east stope the streak has widened from 5 to 13 ft., and the ore is growing richer. In the main body there is 18 to 20 in. of gray copper which assays nearly 300 oz. silver per ton. In the west stope the orebody is from 20 to 22 ft. wide. Eight raises are being made, all of which are up nearly 50 ft. A diamond-drill is to be brought into use at the surface, as a circulation of air must be secured. It will be necessary to sink 1900 ft.——The machinery for the Linn Con. mill is

all in position and the plant will be started as soon as the aerial tramway is ready for the delivery of ore, which should be within 10 days. This plant has a capacity of 50 tons per day, and is built for straight concentration and separation of the lead and zinc ore found in the Mineral Chief mine.——Bowen & Co., leasing on the Sunburst, have started shipments of good-grade ore. Stoping is in progress upon a streak of ore that is 18 in. wide, and the initial shipment milled 170 oz. silver per ton.——M. J. Riley, who is at work on the Grant level of the same mine, has encountered an 8-in. streak of 200-oz. silver ore in the drift recently started to the west. The ground will be in condition in a few days to permit of starting a stope, at which time a heavy tonnage of ore will be mined.——Butts & Co., leasing on the 240-ft. level of the Astor, made another shipment this week that brought a return of 300 oz. silver per ton. ——Lessees at the Santiago, East Argentine, are making ready for a heavy production during the summer months. The bins constructed along the line of the Argentine Central are now being filled, and the capacity of the road will be taxed for several weeks. Harper & Co. are stoping on a 2-ft. body of ore that mills $45 per ton in gold, silver, and copper. Allitude & Co. have a showing equally as good, and two Italians on the fourth level, directly above, have a body of $32 ore that is from 3 to 4 ft. wide.——A big force of men has been put to work in both the Wilcox and Tobin adits, owned by the Waldorf Con. M. Co. Both compressor plants are in operation and a heavy tonnage of ore is being broken.

Georgetown, May 16.

LAKE COUNTY.

The Triumph property, on Breece hill, will be worked at once by L. R. Johnston, who expects to take the ore out through the connection with the Yak adit.——F. L. Loomis has started his contract to advance the face of the Belvidere adit, in the Horseshoe district.

SAN JUAN COUNTY.

The Frank Hough, on Engineer Mtn., will install this spring a new six-drill compressor to facilitate the work on that famous property.——The work of excavation for the Little Nation mill, above Howardsville, is now completed and the floor is laid. A large part of the machinery is already on the ground.——The Stony Pass Co. has resumed work in the Mammoth adit. The face is now in 2200 ft. and will be driven 2000 ft. farther.——The Henrietta property of the San Juan S. & R. Co. will be in active operation soon. The first unit of the mill, the foundations for which were built last fall, will be erected at once.

SUMMIT COUNTY.

The International, at Robinson, has 30 men on its payroll and is shipping 100 tons per day to Leadville and Salida. Since installation of electricity the cost of operating has been reduced, and lower-grade ore is being shipped.——The Ball Mountain Mining Co. has been incorporated to take over and work the old Garibaldi adit, on Ball Mtn., which has been idle for nearly 25 years. Machinery will be installed, the adit re-timbered and driven ahead until the Sunday vein is struck.——Another furnace has been blown in at the A. V. smelter, making a total of six now running.

TELLER COUNTY.

The Mayflower property, near Gillett, will be worked by Horking & Stewart, who will sink the existing 130-ft. shaft still deeper.——McGinn & Conners, who have taken a lease on the Amanda property at Windy Point on Bull hill, are erecting a new hoisting plant on the 200-ft. shaft. They will develop some prospects uncovered by former lessees. ——Three sets of lessees are shipping ore from the dumps of the Moon-Anchor.

IDAHO.

IDAHO COUNTY.

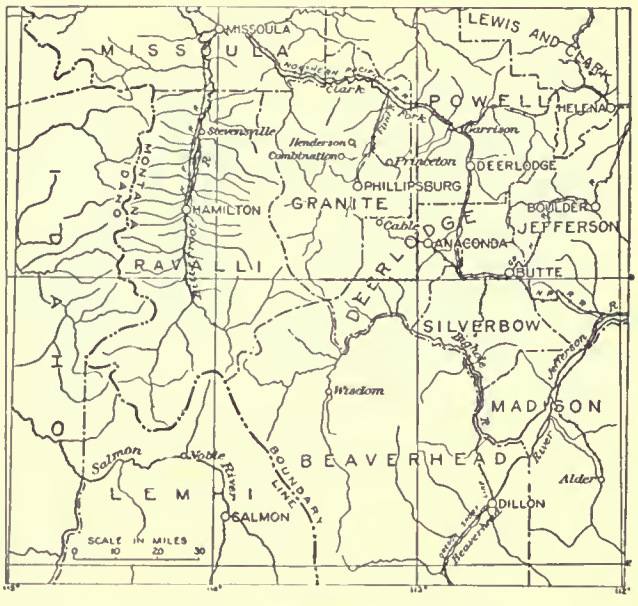
The Elk Gold M. & M. Co. will sink two 100-ft. shafts on their property on the south fork of the Clearwater river. ——The new elevator on the placer property of the Big Sandy Co., near Newsome, was put in operation for the first time last week.——A number of the placer mines surrounding Grangeville are now operating, and more will resume work at once. The snow is melting rapidly and an abundance of water is reported.——The Hogan mine has resumed, with 40 men on its payroll.——The Thunder Mountain Co. has started its new 10-stamp mill.

SHOSHONE COUNTY.

(Special Correspondence).—The Stanley mine, at Burke, is now shipping ore to the New Jersey mill at Kellogg, where 25 tons of ore are being treated daily. About 15 tons per day is being banked to provide against further delays in case the mine closes temporarily.——The National Copper mine near Mullan has struck a vein about 8 ft. wide, carrying copper and silver. Development work is now being pushed in a drift 250 ft. from the foot of a 200-ft. winze.——Four feet of galena, over half of which is shipping grade, has been encountered in a raise from the third to the second level of the Nipsic Mining Co., Ltd., near Burke. The No. 4 adit is to be extended, and it is expected a high-grade body of galena will be encountered. A spur from the O. R. & N. branch line now being run to Murray will probably be built to this district, where several mining properties are already on a shipping basis.

Wallace, May 19.

Galena ore 2 ft. wide has been opened in the Rhode Island property, north of Kellogg. Half of the ore is clean ship-



Montana.

ping grade and the rest of good milling quality. A stringer of good ore 7 in. wide was opened a week ago, and since that time it has widened to 2 ft. The face of the drift is in 275 ft. and has a depth of 125 ft.——Work has been resumed on the property of the Eldorado Co., near Kellogg. The driving of the long cross-cut tunnel is being continued. The adit is now in 275 ft. and it is expected that the main lode on the property will be cut when the adit is driven in 500 ft. ——The Wilbur Mining Co. has awarded a contract for driving 100 ft. of adit, in continuation of the present adit, which was in 200 ft. when work under the present contract was started. The company expects to cut the vein within the next 100 ft., at a depth of 400 ft. The property is situated near the Coeur d'Alene Lead & Silver M. Co.'s property, and lies between the Morning mill and compressor.——Thomas Hololian has begun work on a contract to run 100 ft. of the lower tunnel in the Tam O'Shanter property, which adjoins the Coeur d'Alene Nellie. There are two leads in the claims, and the lower adit has been projected to strike the two orebodies which have been exposed in the upper workings.——The Coeur d'Alene foundry, of Wallace, shipped 8 ore-cars to the Star mine last week.——Development work on an extensive scale is progressing on the property of the Hennessy-Burns Co., near Burke, on the Idaho-Montana line, part of the claims being in each State. The adit now being driven has followed

the vein for a distance of 500 ft. It is estimated that in 150 ft. the miners will strike the second vein.

MONTANA.

The mines of the Butte district produced during April, 21,530,250 lb. copper, which is an increase of 15% over the March production.——The Washoe smelter has contracted to treat 100 tons of ore per day from the Snowstorm mine. ——The Iron Mountain adit, at the Iron Mountain mine, in Missoula county, has been completed, and the unwatering of the mine has begun. The adit, which is 5560 ft. long, strikes the shaft at the 1700-ft. level, below which the water will be pumped.——The Crystal Graphite Co. is preparing for extensive work the coming season at its properties 12 miles east of Dillon, in Beaverhead county.——The Cumberland mine, at Maiden, Fergus county, has been sold to T. L. Lammers and a company of Spokane men, who will operate the mine at once.——The Monitor mine, at Saltese, Missoula county, has been bonded to the Success M. Co. for two years. The bond requires that $60,000 must be spent in development, the shaft must be sunk 300 ft. deeper, and 1500 ft. of underground workings must be driven.

NEVADA.

ESMERALDA COUNTY.

The Pittsburg Silver Peak is to add 50 stamps to its 100-stamp mill at Goldfield.——It is reported that the Bullfrog & Goldfield railroad has passed under the control of F. M. (Borax) Smith and other owners of the Tonopah & Tidewater.——The Rogers-Syndicate lease on the Florence paid the fouth dividend last week, amounting to $30,000. The lease expires July 11.——Another consolidation of Goldfield properties has been effected. The Gold Bar, the C. O. D., and the Victor properties, a total of 90 acres, have been merged under the name of the C. O. D. Consolidated Mines Co., and capitalized at $3,000,000.——The Jumbo shaft of the Goldfield Con. is to be deepened from the 375-ft. level to the 800-ft. mark, at which point it is expected to strike the orebody recently cut in the Mohawk.——The Goldfield mines produced, for the week ending May 16, 1900 tons, valued at $147,500. The Tonopah mines shipped 5570 tons, at an estimated value of $116,200.

LANDER COUNTY.

George Watt has purchased a gasoline hoist for the Spanish Bell shaft, on the property of the Watt Con. Co.——Five tons of high-grade ore were shipped last week from the Jack Pot mine, one mile south of Austin.

LINCOLN COUNTY.

(Special Correspondence).—The Duplex mine, at Searchlight, is being developed and the dump of mill tailing is being cyanided. The mill is to be reconstructed.——A cyanide plant is being built at the Quartette mine, to treat the tailing, a large amount of which has now accumulated. Twenty of the 40 stamps are dropping, and it is claimed a saving of 85% is being made on the amalgamation plates. ——R. J. Stone has leased the Cyrus Noble mill and is doing custom work.——Clayton & Crittenden, who are leasing on the New Year's Gift, shipped 25 tons of ore to the Needles smelter last week. It is claimed that the lowest assay was $78 per ton. The ore is rich in gold, but has enough galena to pay the transportation and treatment charges.

Searchlight, May 16.

LYON COUNTY.

The Gold Center, one-half mile south of Ramsey, has resumed development.——The grading for the Ramsey-Comstock mill is completed and the concrete foundations are being laid.——The Ramsey Con. mine has passed under the control of a syndicate of which Homer Lind of San Francisco is the head.——The Round Mountain No. 1 and three adjoining claims have been sold to H. F. Pierce of San Francisco.

NYE COUNTY.

Thirteen bars of bullion, weighing about 13,000 oz. and estimated to be worth between $50,000 and $60,000, were shipped last week by the Montgomery Shoshone. This represents the clean-up for 29 days of April.——The frame of the Homestake mill is completed and the batteries are set. It is expected that the mill will be running by June 15. ——A strike is reported on the Diamond Queen at Fluorine, which assays as high as $125.——It is reported that C. T. Snedekor has purchased the machinery for a 100-ton custom mill to be built at Manhattan in the near future.

STOREY COUNTY.

Ore from the Chollar and Potosi croppings are to be treated at the Butters plant. The ore will be taken out through the Chollar adit, crushed, and sent to the head of the tramway on a specially constructed track. The lease calls for a daily shipment of 110 tons, but the Butters people expect to treat twice that amount when the work is in full swing.——The Ophir has declared dividend No. 33, payable May 21, the first in several years.

WHITE PINE COUNTY.

The first ore-train from the Veteran mine of the Cumberland Ely dumped its two cars of ore into the bins of the concentrator at McGill last week. The ore was raised through the new four-compartment shaft of the Veteran. Two of the 170-ton locomotives which the Nevada Northern has ordered for the ore-train service have arrived.——The work of clearing the Alpha shaft on the Giroux Con. property is nearly completed and the work of sinking deeper will soon be resumed.——Active work is to be started on the Butcher Boy group of claims. Two shafts are to be sunk near the Ruth mine of the Nevada Con.——Rich ore is reported from the Alvin mine, in the Granite district, north of Ely.

OREGON.

JOSEPHINE COUNTY.

Harrison Bros. have discovered some rich pockets of virgin gold on Williams creek. It is reported that they have cleaned up $30,000 in the last two weeks, and have more in sight.——A 10-stamp mill is to be built at the American Girl and Leroy mines, near Leland.——The Jewett, the principal property in the Mt. Baldy district, will, it is reported, soon be opened.——Work at the Opp mine has been suspended and the 20-stamp mill closed. A cyanide plant is to be installed to treat the tailing.

UTAH.

JUAB COUNTY.

The Eureka Hill shipped 24 cars of ore during April. The shaft is being repaired and will soon be in good shape. ——The Eureka Hill railway received another Shea engine last week.——The Rio Grande railway will run a spur to the lime-rock deposits of the Eureka-Swansea Extension Co. at Robinson. The new smelter at Silver City will use this lime rock.——The following shipments were made last week: Bullion Beck, 3 carloads; Centennial Eureka, 46; Eureka Hill, 10; May Day, 4; Yankee, 4. Total, 67 carloads. ——The Utah Con. has begun sinking a shaft which they expect to be put down 600 to 1000 ft.——The Flying Dutchman people have accepted the terms offered by the Copper Jack for consolidation, and the deal will be finally closed at a special stockholders' meeting to be called at once. The new property will embrace 30 claims, and the three-compartment shaft on the Copper Jack will be sunk 100 ft. deeper.——Work was started last week on the South Swansea with a force of 15 men. The new electric pump has arrived and is being put in.

SUMMIT COUNTY.

The Tantamount Mining Co., recently organized, owns five claims adjoining the Mountain Lake property on the east. They propose to commence development within thirty days.——Preparations are being made for resumption of work at the Silver King Con.——The South Dakota Mining Co. has received a carload of machinery, consisting of a hoisting engine, boiler, and buckets.——The water in the Ontario No. 2 shaft is practically down to the 1500 or drainage level.——The Park City zinc plant is in commission and is said to be successfully treating the ores of the Daly

Judge mine.——A carload of machinery, including a 40-hp. boiler and hoisting engine, arrived last week for the South Dakota property.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Oroville Con. Co. is sinking an incline shaft on the Sunrise copper claim.——At the Grant mine, drifts are being driven on the first vein struck in the lower adit. Work on the main vein has been stopped because of a large inflow of water.——The Kelsey group, on the west side of Osoogoos lake, is being prospected with a diamond drill.——Gray copper and galena, said to be high-grade, have been struck at a depth of 150 ft. in the Rich Bar mine, near Nighthawk. The orebody is 6 ft. in width and is said to contain a large amount of shipping ore.——Returns from two cars of ore sent from the Dividend and Lakeview mines, near Oroville, show a net profit of $25 to $26 per ton in silver and lead.——A concentrator is to be put up on the Okanogan property this summer, and a cable tram is to be erected to carry the ore across the Similkameen river to the Great Northern railway. The reduction plant, which at present consists of a 10-stamp mill, will be increased by the addition of rolls.——Hydraulic machinery for the Milwaukee Golden Sands Co. is expected soon, and operations will be commenced on that company's group of placer claims up the Similkameen river.

Oroville, May 16.

FERRY COUNTY.

(Special Correspondence).—The B. C. Copper Co. is prospecting the Lone Star and Washington claims, near Danville, with a diamond-drill.——The Faithful-Surprise Mining Co., after driving 600 ft. on the vein of the lower adit-level, will raise 220 ft., to connect with a shaft.——The adit of the Hercules mine, at Park City, is in 410 ft. and has passed through nearly 20 ft. of quartz, which contains considerable pyrite and assays about $10 per ton.——Work has been resumed on the Humboldt mine in the Keller district.——Six men are employed on the Railroad group of claims near Laurier, owned by the Mohawk Company.

Republic, May 12.

STEVENS COUNTY.

(Special Correspondence).—The Easter Sunday Mining Co. has been re-incorporated under the name of the Forrest Mining & Milling Co. The capital stock of the new company is $1,200,000. The Easter Sunday group is in Pierre Lake district.——The No. 3 adit on the Trojan mine is slowly progressing, with three men employed. It will cut the main vein at a depth of about 500 ft.——An adit on the Mohawk mine, near the head of Pierre lake, has been driven 40 ft. on the vein. The vein at the face is six feet wide, all gold and silver-bearing ore, between walls of granite and porphyry.——The North Star Co. is building a superintendent's residence, a bunk-house, and a blacksmith-shop at its property on First Thought hill. A contract has been let for a new adit.——At the Trophy mine the adit is in over 140 ft., leaving 60 ft. more to drive on the present contract. It has passed through slate and phonolite, both formations dipping into the hill. The adit has cut into a contact with porphyry, along which pebbles of iron ore have been found.——A blower has been ordered for the adit at the Globe mine near Orient. Rowland T. Irwin has been appointed manager, and the company is planning to operate on a much larger scale than heretofore.——Eight feet of lead-silver ore has been encountered on the Silver Star property in the Northport district. A crew of 10 men is now being worked there.——A new and rich strike is reported at the Scotia mine.——Three carloads of rich gold-bearing ore was recently shipped to the smelter at Trail, B. C., from the First Thought mine. One of the stopes now shows a 30-ft. face of 10-oz. gold ore. The ore produced last month was of better grade than any ever before shipped from the mine.——Work has been resumed on the 200-ft. level of the Jay Gould mine, in the Chewelah district.——Four 4-horse teams are employed, and 40 to 50 tons of ore, rich in copper, are being shipped daily from the United Copper mine. The company is employing 19 men. The winze from the 400-ft. level is down 50 ft., and a cross-cut from the bottom has developed nine feet of shipping ore. The greater the depth in the mine the better is the ore and the larger the value in both silver and copper.——A new hoist and seven-drill compressor have been purchased by the Chewelah Copper Co. to sink to a depth of 500 ft.——The Blue Star Mining Co. has been organized and has taken over the stock of the old Eagle Mining Co., the holders of which will be protected under the new deal. The Eagle mine is fully equipped with machinery and was at one time a large shipper. Mark Mitchell is the new president and manager.

Spokane, May 12.

CANADA.

BRITISH COLUMBIA.

The Eureka, at Sandon, has re-opened with a pay-roll of 35 men.——The Queen mine and mill, near Salmo, has been sold to Wisconsin capitalists for $175,000. The Queen ore is free-milling. The mill is equipped with a 10-stamp battery, to which 10 stamps more will be added as soon as they can be hauled to the mine from the railway siding, where they now are.——The B. C. Copper Co. is hiring men for its mines and smelter, which opened last week after being shut down since November 12.——The Little Bertha, at Brannock

Centre Star Mine, Rossland, B. C.

City, reports a strike of a 2-ft. vein assaying over $500 in gold and silver.——It is reported that the steam shovel on Pine creek, near Atlin, which is operated by the Guggenheim interests, will start operations soon. The C. A. C. coal mine, at Frank, is to be opened at once. Forty men are now at work repairing the tipple and getting things in shape.——The B. C. Copper Co. has resumed operations at its Mother Lode, Emma, and Oro Denoro mines and at its smelter near Greenwood, employing about 600 men. They expect to pay about the same scale of wages as now in force at the Granby Con.——The Granby ore shipments for April amounted to 87,200 tons.——Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending May 9 and for the year to date:

Mine.	Week.	Year.
Centre Star	3,200	63,678
Le Roi	1,400	31,049
Le Roi No. 2	315	10,344
Blue Bird	20	80
Red Eagle	....	20
Evening Star	....	428
California-Giant	....	60
Totals	4,955	105,659

The receipts of ore at the smelter of the Consolidated Co., at Trail, during the past week totaled 6308 tons. Besides the ore from the Rossland camp, shipments from other mines were received as follows: Snowstorm, 1207 tons; First Thought, 256; North Star, 128; Richmond, 59; Rambler-Cariboo, 23; Vancouver, 20; Reco, 20 tons.

Special Correspondence.

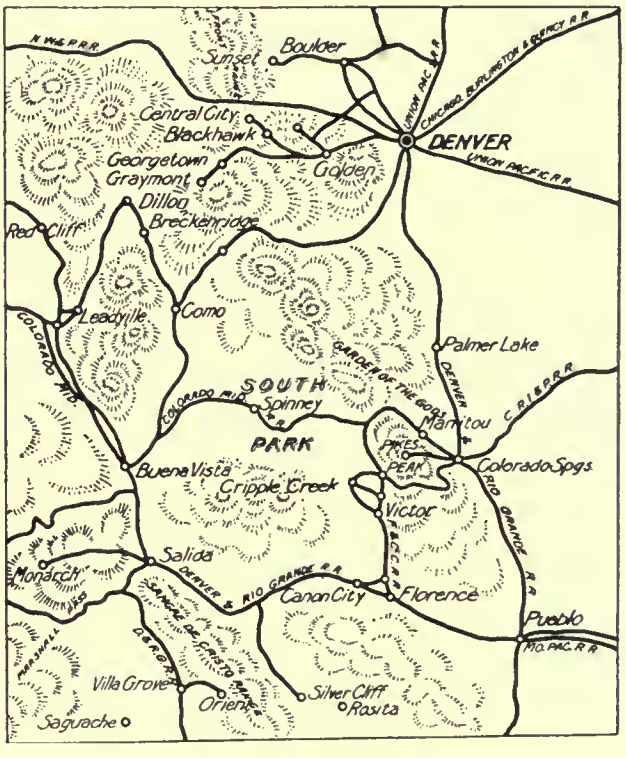
LONDON.

Stratton's Independence. — Methods of Reorganization. — Spanish Coppers.—Waihi Production.

The present position of Stratton's Independence, Ltd., is an apt illustration of the desirability of always keeping plenty of funds in hand during prosperous times to provide for the proverbial rainy day. It is difficult to persuade the ordinary run of shareholders that this is the right policy. Most shareholders seem to consider, after the event, that investment in a mining share is the height of folly and that they must get their money back at all costs. It is often the case that shareholders grudge the laying up of a large balance, or reserve fund, considering the existence of such a balance a sort of dodge of the directors to plunder them. Three years ago the directors of Stratton's Independence were averse to the further distribution of dividends until the prospects of the mine were more exactly ascertained, and they wished to keep intact the balance in hand of something like £100,000. The shareholders publicly and privately created so much ill-feeling on the subject that the directors consented to make a distribution of £75,000, contrary to their own judgment, with the consequence that on June 30 of last year the balance in hand had been reduced to £39,000. This has proved insufficient to develop the resources of the mine on the new system and to install the modern cyanide plant designed by Philip Argall. As you have recorded in your columns already, the new plant is of first-class design and is now in excellent working order. Not only will it treat the old dumps, but it will also separate the friable rich ore by coarse crushing and sizing. The company now finds itself in the extremely awkward position of not being able to meet the whole of the indebtedness incurred in the construction of the mill. A further sum of at least £28,000 is required. Of this, £10,000 was originally provided for the mill, but was spent on the mine; another £2000 is required for mill construction over the original estimate, and £16,000 is required for further expenditure on the mine and for working capital. In addition to this total, it is desirable to have further funds to allow of erecting without delay the second unit of plant for treating the dump-ores. The directors are therefore proposing to ask the shareholders to put up £50,000. The scheme is to issue debentures to this amount carrying 6% interest and entitling the holders to a further 19% as bonus. This really means that the debentures are to receive 25% per annum. These are onerous terms and are much of the same nature as those ruling in the case of the Cerro Muriano, to which I referred in a recent issue. It means that the shareholders must take up their debentures or be left out in the cold, for the interest and bonus on the £50,000 debentures amount to £12,500 per year, which is as much as the new plant is estimated to yield in the way of divisible profit.

This incident leads me to mention that the present state of the law relating to assessment by reconstruction is somewhat uncertain, owing to recent judgments in the High Court. The old way of doing things was to form a new company, issuing shares, partly paid, in exchange for the fully paid up shares in the old company. If shareholders did not take up their new shares they lost all interest in the new company. It was supposed that if the reconstruction scheme was passed by a three-fourths majority, the dissenting shareholders had no further rights, but according to recent decisions it has become difficult to deal with a reconstruction unless voted unanimously. It would not interest your readers if I went into details as to the rights which dissenting shareholders are now supposed to have. It is sufficient for my present purpose to point out this difficulty as the reason for directors adopting different methods of bringing shareholders up to the mark.

During the last few weeks I have referred to several copper mines in Spain that have given dissatisfaction. To those mentioned I must add the San Miguel. This mine is in the Province of Huelva. It was worked for some years by local owners, and in 1904 was acquired by an English company controlled in Germany. For some time this company appeared to be doing well, and dividends were paid regularly. In 1906, however, a bad accident at the mine revealed the fact that there was a good deal of mismanagement, and the board of directors eventually resigned in the autumn of 1907. The new board, under the chairmanship of Nicol Brown, has reorganized the work in many departments and has put things in much better shape. In their investigations the new board found many irregularities in the old way of keeping accounts. For instance, bad debts were not allowed for, and ore in stock was valued at selling price and not at cost. It was thus made to appear that the assets were greater than they really were, leading to the payment of dividends not really earned. In overhauling the balance sheet of December 31, 1906, the new directors found that in a number of items the figures were too high, and have deemed it desirable to write off £15,055. The result is that the dividend of £17,500 distributed on the year's



A Part of Colorado.

working has been unearned, and a deficit of £10,522 made. The case is so bad that legal proceedings against the old directors are contemplated, with a view to recovering from them personally the unearned dividend. The results for 1907 have not been satisfactory, owing to it being necessary to spend money in making good the results of the accident mentioned and in changing the method of treatment. The fall in the price of copper has also adversely affected profits. The present board has found it better policy to increase the leaching operations instead of selling so much of the copper-bearing pyrite. In the long run a better price will be obtained in this way, though for the first year or two the lock-up of copper will decrease the returns. The output of ore in 1907 was 45,462 tons, of which 34,432 was added to the heaps for leaching, and 11,030 prepared for export. The production of precipitate was equal to 367 tons of fine copper, and the deliveries of washed ore were 25,000 tons. When the improved leaching operations are in full working order the output of copper should be about 600 tons a year. Nicol Brown is chairman of the adjoining Peña mine, which is also largely owned in Germany, and under his direction the San Miguel should be pulled round satisfactorily.

I think that it may be taken for granted that at the present time the Waihi in New Zealand is the greatest gold

mine of the world, not so much on account of current production or of its past history, but because of a combination of these two with the outlook for the future. As I said recently, the more development work done, the more stupendous are the ore deposits discovered. During 1907 the tonnage milled was 356,974 short tons dry weight. The recovery was 141,038 oz. fine gold and 773,434 oz. silver. In addition 27,368 oz. gold and 335,318 oz. silver was obtained from the concentrate and 315 oz. gold and 10,541 oz. silver from the slag tailing. The total production was 168,722 oz. gold and 1,119,294 oz. silver, which sold for £878,485. The working costs, development, and office expenses were £357,674. In addition, £53,299 was spent in sinking shafts and in new plant, £35,012 was written off for depreciation of plant, and £31,893 reserved for income tax. The amount distributed as dividend was £396,725, being at the rate of 80% on the issued capital. The mine has been in operation since 1887, but production did not start actively until 1890. In 1892 the yield was valued at £46,219, since when the figures have slowly mounted up to the present level, and the total metals won have sold for £6,290,113. Dividends were first distributed in 1893, and the total to December, 1907, has been £2,693,073. It is impossible to give an exact estimate of the ore reserves, and no attempt is made to do so. It is only necessary to say that the mine really consists of a group of three or more mines, and that at a number of points there is enough ore to feed the mills for years to come.

JOHANNESBURG, TRANSVAAL.

White Labor Experiment.—Gold Law Drafted.—March Gold Output.—High Tube-mill Duty and Low Costs.

The white labor experiment in the mines has proved almost a complete failure. Of the 400 men for whom work was promised, only a few remained longer than a day or two. When they found what terms were offered, most of the unemployed picked up their bundles and started out on the road again. The few that stuck to the work are now earning from 4 to 5s. per day. The men are not entirely to blame for the fiasco. There was bungling somewhere. When the mines offered to take on 400 men, they should have explained the terms and conditions more fully. There should also have been a more helpful spirit shown on the part of the mine managers, and a determination to make the experiment a success. The terms offered the men were in some cases not quite fair. At a few of the mines the unemployed were offered ½d. per inch on hand-drilling, or 1s. 6d. for the usual 36-in. hole. Very few of the men had ever done this work before, but were accustomed to shoveling and tramming, and should have been put to work where they could show the best results. It must be admitted that a large number of the men went to the mines on the off-chance of picking up a highly paid job, and were disappointed when it was not forthcoming. Many of them had no desire to do "Kaffir's work." In other cases some of the unemployed might have succeeded had they received more encouragement from the mine officials. It is to be feared that some managers looked upon the experiment as a nuisance, and were pleased when it failed. All interested in the welfare of South Africa deplore the failure of this experiment. It is imperative to do something to extend the field of employment for white men in this country. It is also necessary to dispel the idea that the white man is an ornament in the industrial life of the country and need only be a supervisor of Kaffirs. He must learn how to work. The champions of the scheme have not despaired yet, but are still trying hard to get work for the unemployed whites. Another attempt will be made to place some of the men in the mines at work where they can earn a fair day's pay for a fair day's work. One mine will try to replace its Kaffir labor with whites in the discharging of sand from the cyanide works.

The native labor returns show that the labor position improved during the month, the net gain being 4015. The number distributed during March was 15,245, against a total wastage of 11,230 due to Kaffirs returning home. Against this gain of 4015 natives must be placed the loss of 1902 Chinese coolies, leaving a balance to the good of 3113 for the month.

The draft of the new gold law has been published, and people feel rather relieved, for although there are some changes, there are none of the socialistic innovations that might have proved disastrous to the country. Before it becomes law, there will be a complete discussion on the new gold law before the next session of Parliament at Pretoria.

The results achieved by the gold mines for March are most satisfactory. The total output from all the Transvaal mines amounts to 574,901 oz., valued at £2,442,042, which is an increase of 32,971 oz. above the February output. The Rand's contribution to the output was 553,440 oz., valued at £2,350,865, while the outside districts contributed 21,461 oz., valued at £91,157. It is the largest production yet recorded as the result of one month's work. The record month of last December, with 583,526 oz., valued at £2,478,659, included some 40,000 oz. of reserve gold turned in by the mines of the Central Administration and Rand Mines group, and yet the March yield is only 8625 oz. behind the swollen return for December. The total number of stamps at work for the month was 8830, of which 8435 were crushing on the Rand.

As usual the Robinson mine heads the list, as regards profits, and working cost per ton crushed, although the

Street in Johannesburg.

Simmer & Jack is first in total production. The profit made by the Robinson was declared to be £80,062, while that of the Simmer & Jack was £63,844. The only company reporting a loss for March was the Lancaster. A new record in working cost was established by the Robinson mine, which reports the cost per ton at 13s. 0.062d. per ton milled. The conditions at this mine are ideal, which explains the improvement in economy. Good though this figure is, there is every reason to believe that it is not the lowest attainable.

The average working cost for the Central Administration, embracing eight of the leading mines, is the lowest on record, namely, 17s. 7.77d., including everything (development, head office expenses, etc.)

Tube-mills helped the output considerably during the month, 70 being at work on the Transvaal mines. The Luipaard's Vlei Estate mine got the high duty of 9.2 tons per 24 hr., while a number of the mines show 8 tons per day and over. The percentage of waste rock sorted varied from nil to 35.63 per cent.

SALT LAKE, UTAH.

Graselli Chemical Co.—Tintic Resumption.—Swansea Consolidated Formed.—Park City.—Mercur Output.

The Graselli Chemical Co. is now operating its zinc-mill at Park City, treating zinc middling from the Daly Judge mill, the Sutton, Steele & Steele process of dry concentration being used. The smelter at Ogden, owned by the Utah Smelting Co., has been leased to a syndicate of Salt Lake and Ogden parties, who will operate it along independent lines. The plant is equipped with one furnace of 250 tons

daily capacity, the ore being reduced to a matte. It is said a second furnace, and possibly a reverberatory, will be installed. Custom ores will be treated, and an effort is being put forth to obtain common-point rates on ores from camps south of Salt Lake City. J. B. Jensen of Salt Lake will be manager. The Ogden smelter was operated for several months last year, proving to be a failure financially, but a success metallurgically.

The ore-purchasing department of the Tintic Smelting Co. will open for business and begin the purchase of lead ores for treatment in the new Tintic smelter, the lead furnaces of which will be ready to go into commission in the early part of June. It is stated by the manager that it will probably be August before the copper furnaces will be ready to receive ores. The lead department will handle 400 tons of ore and fluxes daily. On June 1 the final details will be arranged for a merger of the Swansea and South Swansea mines in Tintic under the name of the Swansea Consolidated Mining Co. These properties have been idle for a number of years; new equipment has been installed and by the time the Tintic smelter is ready for operation the combined property will be in condition to resume production. Ore shipments from the Park City mines last week amounted to 334 tons, the Daly Judge and Silver King Coalition producing 167 tons each. The citizens of Park City, to show their appreciation of the great work accomplished by the management of the Ontario and Daly Mining companies in successfully restoring the Ontario drainage adit, have planned a popular demonstration. They believe the date of the re-opening of the adit marks the beginning of a new epoch in the history of the camp's progress. The April earnings of the Consolidated Mercur Gold Mines Co. has been given out as being $65,000, which is the result obtained from the operation of the mill treating 800 tons of ore per day. The fourth portion of the Boston Consolidated concentrating mill at Garfield, Utah, is practically ready for operation, and will probably be placed in service June 1. The Little Beaver Mining & Milling Co., operating in Beaver county, has leased the 20-stamp mill of the Estella Gold Mining Co. near Milford and placed it in commission.

Another blast furnace is to be installed at the Yampa smelter within the next fortnight. The Yampa is now handling 800 tons of ore per day, and it is expected that this figure will be increased to 1000 by July 1, when the new converter will be ready for use. After that the blister copper will be made at the plant, instead of shipping the matte.

BISBEE, ARIZONA.

Copper Queen Con.—Complete Change in Method of Handling Ore.—Central Power Plant.

At the Queen property for a considerable period extensive improvement and construction has been going on, both underground and on the surface. The greater part of this work is in preparation for a complete change in the system of handling the ore, together with the installation of an economical and thorough electric equipment over the entire property. The ore is at present hoisted through five shafts. The power for the property is likewise produced at a number of individual plants widely scattered. In the near future the ore will be hoisted through one centrally located shaft, the Sacramento; and the power for the property will be generated at one main power plant. With this end in view, the Sacramento shaft has been sunk to a depth of 1200 ft., and will within a few weeks be connected with all the other underground workings by drifts, in which traffic will be concentrated. These drifts will serve every level from the 400 down. At the same time a thoroughly equipped modern power plant has been under construction, and is now practically complete. Up to the present the ore has been transported to the different shafts by man or mule-power; the individual cars run onto either two or three-deck cages, hoisted to the surface, and from there pushed by hand varying distances, and dumped into the railroad cars to be taken to the smelter at Douglas.

With the new system installed, the old shafts will be used only for handling men, timbers, and waste. The ore will be drawn by motors to the new Sacramento shaft through the haulage drifts, which will be used exclusively for long-distance haulage. For the present there will be about five and one-half miles of these drifts in use. The motors are made by the Goodman Co., weigh two tons each, and are expected to handle about 10 tons of ore per trip, running at the rate of 6 miles per hour. At the shaft the ore will be dumped into 50-ton ore-pockets, and hoisted through two compartments in skips with a capacity of 60 cu. ft. each. From the skips it will be dumped into hoppers, and from these, by means of a belt conveyor, carried directly to the railroad cars.

At the Sacramento a first-motion Nordberg hoist will be used, with round rope and cylindrical drums. The drums are 7 ft. diam., with 5 ft. face, and are connected to the main shaft by friction clutches operated by hydraulic pressure. Post brakes are used, also controlled by hydraulic pressure. The hoisting engine is a double, compound, tandem, condensing-engine made by the Nordberg Co. The erection of the hoist is well under way. At present the five main hoists, and an equal number of dinkey hoists, are run by steam power generated at the individual shafts. There is a saw-mill at each one of these shafts, with its own small engine, using steam for power. Thus far, air for use underground has been compressed at the old power-plant near the Czar shaft, and at the Lowell shaft. Electric power for general use over the whole property has been generated at the Czar power-plant and at the Spray shaft. The pumps underground are run either by steam or by electric power, most of the water being handled by steam pumps. The small hoists underground use either air or electric power. To do away with these unnecessary plants and to simplify, enlarge, and cheapen all power production, the new power plant has been built. The purpose of this plant is threefold: first, to produce steam for operating the machinery in the plant proper, the Gardner hoist, and the Sacramento hoist; second, to compress air for the machine-drills underground over the entire property, and for power to run the Holbrook, Spray, and Lowell hoists; third, to generate electricity for the underground haulage system, the Czar hoist, electric lighting of mines and buildings, and for operating all the smaller machinery connected with the mines, including saw-mills, machine-shop, small timber-hoists underground, blowers for ventilation, etc. This new power plant contains four 400-hp. Stirling water-tube boilers, equipped with Foster superheaters and Greene fuel economizers. The working pressure is 150 lb. Oil is used for fuel. There are two 25-hp. plunger feed-pumps, electrically driven. The two air-compressors are of the cross-compound type, each rated at 3500 cu. ft. free air displacement per minute. The high and low-pressure steam-cylinders, made by the Cooper Co., are respectively 19 and 40 in. diam. The stroke is 48 in. The air-cylinders, which are of the Ingersoll-Rand make, are 21½ and 35½ in. diam., respectively. The working pressure of the air is 100 lb. per sq. in. Later a third compressor will be added, which is now in the old power-house at the Czar. This is an Ingersoll-Rand with a capacity of 1700 cu. ft. per min. There are three 500-kw. Curtis vertical steam turbines, generating an alternating current of 2200 volts. A portion of this current will be converted at the power-house to direct current at 250 volts, by two rotary converters. This part of the electric power will be used mainly for underground haulage. The rest of the power will be distributed by alternating-current lines at high voltage and transformed at various points, as its use requires. Two of these turbines will be kept constantly in operation supplying 1000 kw. Both compressors and turbines are equipped with barometric condensers. The circulating water for the condensers is pumped by the Connersville rotary pumps, of which there are three driven by 60-hp. variable-speed direct-current motors, regulated by a float in the hot-well. This water is pumped from the hot-well to a cooling-tower, from which it flows by gravity to the condensers. It is expected by the management that early in July the entire new system of handling the ore will be in operation, and all the production of power will be centralized in the one main power-plant.

JEROME, ARIZONA.

Drainage and Ventilating Adit.—Rapid Driving.—Working Fire-Stopes.—Additions to Smelting Plant.

The new drainage and ventilating adit of the United Verde mine, at Jerome, Arizona, will be 6600 ft. long, and will connect with the mine at the base of the new 1000-ft. shaft. It has been driven 3800 ft. from the portal, on the mountain slope that overlooks the Verde river; and 800 ft. from the shaft. The adit will have a uniform grade of 0.5%, the cross-section being 7½ ft. high by 8½ ft. wide. The lower section of the work is in the limestone country and the upper end has passed through quartz-porphyry, which is the mineral-bearing rock of the district. The heading from the shaft-end is now close to the contact of the quartz-porphyry with the lime; the work here is also cutting through a water-course. In driving this adit, on the lower section, two shifts of machine-men with Ingersoll drills, with two chuck-men to a shift, followed by three shifts of shovelers with three men per shift, have averaged 9.1 ft. per day for the year. They have driven as much as 87.5 ft. in one week. All the rock is transported to the portal in cars hauled by mules. The drills are run by an electrically driven air-compressor. At a point 1800 ft. from the mouth of the adit is a raise which taps a creek-bed above, the water from which drives a Pelton wheel, generating sufficient power to operate a Sturtevant fan, which discharges the gases into the raise above and draws pure air to the breast of the adit from the portal, through a 22-in. pipe. By this method it is stated that the smoke from 15

United Verde Smelter at Jerome, Arizona.

charges of explosive is cleared from the workings in 20 minutes. The drill-holes average 6 ft. deep. The driving on the shaft-end of this adit has been attended by more difficulties in ventilation by reason of the high temperature of the air in the workings above. Ventilation is accomplished here by electric fans, conveying air through a pipe 11 in. diam. In driving this end of the adit timbering and board-lagging has to be maintained up to the heading, the timbers being set 2 ft. apart, centre to centre. All the mine drainage, and the water from which copper in solution is to be precipitated, will be passed to the 1000-ft. level, thence out through this adit, there being a box channel in the bottom for the purpose. At the mouth of the adit this copper-bearing water passes into a precipitating flume 5 ft. wide and 10 in. deep, having 0.8% grade. The flume will be half a mile long, with settling-boxes 120 ft. apart. The precipitation will be accomplished with scrap-iron. The mine-workings are everywhere timbered with square sets, filled closely with waste. The 'fire-stopes,' that is, those in which the sulphur in the ores is burning, are being successfully worked at the 300-ft. level by air being blown to the face, driving the gases back into the old workings. Without these strong currents of fresh air, forced in by electrically operated fans, the atmosphere in the fire-stopes would rise to 180 or 220°. The fire in those stopes which are not being worked is confined by cement bulkheads with steel gates. The ores are on fire in various places from the fifth level to the surface.

In the smelting plant two 550-ton furnaces are operating all the time, and a third furnace of equal capacity a part of the time. A new 20-ft. furnace has been set up, and a new blowing engine is being installed to supply the blast. Two new stands of converters with cast-steel heads are being installed, the mechanism of which will be electrically operated. The ores here are not roasted.

PIOCHE, NEVADA.

Jack Rabbit.—Improved Railroad Facilities.—Geology of Day Mine.—Extensive Development.—New Plant.

In spite of the depression due to prevailing prices of silver, lead, and copper, there is much activity in this district. This may be attributed to two conditions: first, the ores of the district are of such character that they may be mined with profit even at prevailing metal prices; and second, that none of our mining men believe that present prices will continue. The bulk of the shipments this year have been from the Jack Rabbit mine of the Nevada Utah. Although located as the Jack Rabbit, and so appearing on the records, this mine is generally known and referred to as the 'Day.' The mine was discovered by Isaac Newton Garrison in 1877, after the decadence of the great properties at Pioche. In walking over the hill Garrison saw a jack rabbit. He stooped down, picked up a rock to throw at the rabbit, and found that he had a piece of ore in his hand. The deposit was soon located and named the 'Jack Rabbit.' It was exceedingly rich on the surface, and was soon purchased by Capt. H. H. Day, who had been manager successively of the Meadow Valley, the Raymond, and the Ely companies. The principal owners were San Francisco men, but Mr. Day ran the mine for years and extracted hundreds of thousands of dollars from the group, other claims having been purchased. It became the custom to speak of the property as 'The Day,' and the pseudonym has survived. When James P. Gaskill, chief engineer of the Nevada Utah, assumed charge of the mining operations for that company on January 1, he concluded that the Day was the most promising of all the properties for immediately profitable output. He has given it his undivided attention since that time. A narrow-gauge railroad nearly 14 miles long connected the property with the broad-gauge branch of the Salt Lake line, opened to Pioche January 1. This narrow-gauge line has been practically re-built, a new engine and other equipment purchased, and for some months there has been a double daily service. It has been bringing in about 100 tons daily from the Day and several standard-gauge carloads weekly for the Bristol Consolidated, which resumed operations several weeks ago. It is the intention of the Nevada Utah to make this narrow-gauge a custom road, and to haul ore and supplies for any company desiring to patronize it.

The Day mine is in Cambrian limestone. The main adit is on the third level. A shaft at the mouth of the third level has been sunk to the twelfth, proving that the limestone persists below that depth. Three fissures nearly vertical and approximately parallel, striking about N20°E, constitute the main vein-system of the Day. These intersect a transverse system of fissures, and also the bedding-planes of the limestone, which dip from 20 to 30°. The ore occurs as a replacement in the limestone at or near intersections with both the transverse veins and bedding planes, and also sometimes follows the bedding-planes for considerable distances from the main veins. The main tonnage is furnished by ore carrying from 10 to 20 oz. silver, 5 to 15% lead, and so high a percentage of iron and lime that at 10c. per unit the iron and lime often come near paying freight charges from Pioche to the smelter. Some weeks ago an irregular orebody of high grade was found. One car of 25 tons was shipped, which netted at the smelter about $118 per ton. Scattered through this body were pieces carrying bromide and chloride of silver, which assayed up into the thousands of ounces, and afforded welcome opportunity for Eastern brokers to indulge in spectacular advertising. Mr. Gaskill is working out a system of development which will make the main working shaft

on the Onodago mine. The collar of this shaft is several hundred feet lower than that of the present working shaft. He is going to add to his plant immediately two large compressors and two boilers, connect one of the lower levels with the Onodago shaft, dispense entirely with the bucket-tram from the third level, and install a powerful hoist on the Onodago. He expects to be able to deliver ore to the bins at a total cost of not over 50c. per ton. This suggests the enormous orebodies in which he expects to mine and the insignificant cost upon which he is counting for mine-timbers. Large as is the tonnage to come from the Day mine, the management of the Prince Consolidated Mining & Milling Co. is confident that still larger bodies of commercially valuable ore exist in the Prince mine, three miles southwest of Pioche. They talk of an orebody 80 ft. wide, carrying an average of 6% lead, 8 oz. silver, $1.50 gold, and 32% excess iron and manganese. This company has recently also found a vein of high-grade ore, running nearly parallel to the manganese ore, which has been explored for a length of about 110 ft. On the south end of the drift there is now 4 ft. of ore. Toward the north there are indications of a system of veins of this character; but further development will be required to determine the extent. From the assays of ore already taken from this vein, the shipping product should show 100 oz. silver, $10 gold, and 30% lead. This company will install at once a new 100-hp. compressor plant.

The same interests which control the Prince Consolidated also control the Ohio-Kentucky, a property of vast possibilities. At present the Ohio-Kentucky Mining Co. is devoting its attention chiefly to the Susan Duster, a silver-lead-zinc property about half a mile south of Pioche. This company is planning to install a concentrator to effect a separation of the lead from the zinc. The same interests also control nearly 200,000 tons of old tailing at Bullionville, about 10 miles southeast of Pioche, where the old mills were located which treated the ores from the Pioche mines in the early days. These interests are working on a plan for a smelter at Bullionville in which the lead sulphide from the Susan Duster and the iron-manganese ores from the Prince shall enable them to smelt their tailing and also to purchase silicious ores from other mines in the district. The Boston & Pioche mine, situated about a mile southeast of Pioche, is in high-grade ore on three levels. This company owns about 4500 ft. on the old Yuba dike, which runs easterly and westerly a short distance south of the great Meadow Valley Raymond-Ely vein. The porphyry dike in quartzite, dipping about 70° south, has three distinct veins, one on each contact, and one in the porphyry. Sometimes only one of these veins carries value, sometimes two, and occasionally all three. It is said that in the early days, when the mines here were all working, one could walk on ore continuously for a mile in this dike. The Boston & Pioche has on each level about 18 in. of high-grade ore, which C. S. Miller, the manager, claims will run about $100 per ton in gold, silver, and lead. There will also be from two to three feet on each level of low-grade ore, which will be reserved for treatment later, when the company erects a concentrator. The company is now installing a new 100-hp. engine and air-compressor.

The Nevada-Des Moines Mining Co. has the head-frame ready for a 40-hp. gasoline hoisting and compressor-plant, which is due to arrive any day. This is the company which took out some cores with a diamond-drill which they claim yielded $1000 per ton in gold. The community is waiting with impatience for the shaft which may confirm this claim, or extinguish exalted hopes. The Nevada Pioche Mines Co. was organized here last week to take over the old Page & Panaca mine, which had a brilliant record in the early days. Some prominent Ohio men hold control, represented by E. Greenwood as manager. The famous Mendha, in the Highland district, has ordered a 40-hp. hoisting and compressor-plant, and will commence shipping as soon as it is installed. The Ely Mining & Milling Co. and Nevada Horn Silver Mining Co. are developing properties which make some gratifying disclosures, and a number of other properties are preparing to ship on a small scale.

BUTTE, MONTANA.

Cost of Producing Copper.—North Butte.—Davis-Daly Estates.—North Butte Extension.

It is asserted by men whose judgment is good that the average cost of Amalgamated copper is below 10c. per lb., including refining and selling. The Amalgamated not only markets its own copper, but also that of the North Butte and the Butte Coalition Co. The two latter companies are mining a quality of ore that for richness has never been equaled in Butte, and but for the fact that they are required to mix with it a lower grade, they could market copper at an exceedingly low cost. The extreme high cost of Butte copper during the past two years was due entirely to the heavy expenditures for immense new plants and improvements. In the case of the North Butte Co. the great amount of exploration and development work ran the cost up, but that work has been carried many years in advance. In the case of the Butte Coalition Co., entire new surface plants of a type that will not require additions or enlargements for many years were installed and charged against production, while the mines were in a frightfully bad condition, left so by the former owners—the Heinze companies—which mined ore during the last year of possession regardless of consequences and reckless as to timbering. In many instances it would have been cheaper to have opened new mines than to pick up and put in condition the old workings. This work was done at great expense, and at the same time extensive development and exploration work was carried forward. All this extraordinary expense was marked up to the cost of production. The mines are now in as good condition as any in the Butte district, and all the extraordinary expense has been cut off. Only the ordinary development work is kept up, and immense new bodies of high-grade ore, much of it copper glance, have been opened. The levels of the Minnie Healy mine will shortly be connected with the new Tramway shaft, when the latter will be used for mining the Minnie Healy below the levels troubled with smoke and fire. The Minnie Healy veins have been cut and opened on the lower levels and the ore tonnage will be more than doubled when the tramway hoist is put in commission. No recent strikes have been made in the Coalition mines, but the ore reserves are showing up larger and richer. There have been reports also, emanating from Wall Street, of new strikes in other Amalgamated mines, but these stories appear to have been manufactured for stock purposes exclusively. No exploration is being done in any of the Amalgamated properties at present, and the development is confined to the veins and orebodies that were opened by sinking and cross-cutting a year ago.

The re-election of the old directors of the Davis-Daly Estates Copper Co., with the addition of three men closely associated in business with, or as employees of, Heinze and Coram, seems to preclude the likelihood of any more confidential relations between the stockholders and the management in the future than in the past. A portion of the public which bought Davis-Daly stock at prices from $12.50 up to $17, has been uneasy over the disclosures concerning the affairs of the company and the discovery that it had no funds in the treasury, when the public was led to believe there were several million dollars in hand. There is something of a question whether the public was tricked or self-deceived. When it was eager to buy Davis-Daly stock it refused to read anything but boom news about the property, and a few items of truth were denounced as 'knocks' and untruths, but it now develops that the stories of immense orebodies opened last year were mostly imagination, as were the stories of a big treasury balance. The company is still pressed for funds, and is carrying on only a limited amount of work.

A 500-gal. pump has been installed on the 500-ft. level of the North Butte Extension, and the water, which impeded sinking for a while, can now be handled easily. A new electric pump for the 700-ft. station will arrive about July 1. It has not yet been definitely decided to cross-cut at the 700-ft. level.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Molybdenum, occurring usually as the sulphide, molybdenite, which strongly resembles graphite in appearance, is commonly found in association with pegmatite dikes in granitic areas. It is also a not uncommon mineral in silicious copper ores in certain districts of Arizona and Canada.

The supporting power of a pile, two thirds of which is in the ground, can be determined by the formula given in Baker's 'Masonry Construction,'

$$P = 100(\sqrt{Wh} + (50d)^2 - 50d)$$

in which P is supporting power, in tons; W, weight of the hammer, in tons; h, height of fall, in feet; and d, penetration of the pile under the last blow, in feet. The test blow must be measured on sound wood, and it is best to use the average of several blows.

Mica occurring disseminated in igneous or other crystalline rocks is commonly an original constituent, whereas when occurring in large masses, capable of commercial use, it is invariably a secondary mineral, resulting from alteration of orthoclase cyanite, corundum, and other minerals, present in extensive segregations. Such alterations usually occur at a considerable depth below the surface, hence the extent of the mica will depend upon the extent of the original segregation.

Arsenic sulphide may be recovered by lixiviation with a solution of soda, according to F. Howles, who describes a process in the *Revue Chimique*. By using the soda or other alkali, sulpho-arsenates of the alkali metal are formed. The solution containing these can be decomposed preferably while warm, by iron or manganese hydroxide; the sulphur of the sulpho-arsenates is thus replaced by oxygen, forming commercial arsenite in solution and a precipitate of iron or manganese sulphide, which can easily be filtered out. The arsenites can then be recovered by evaporation of the filtrate.

Vanadium is sold on the basis of the vanadic oxide (V_2O_5) contained in the ore, the current quotation being 40c. per lb. of vanadic oxide, the minimum amount admissible in a commercial ore being 12%. The commonest ore is the mineral vanadinite, a chloro-vanadate of lead, which contains 19.4% vanadic oxide in the pure state. Descloizite, a hydrous lead-zinc vanadate, containing 22.7% vanadic oxide, and roscoelite, a complex silicate of the mica group, containing over 20% V_2O_5, are also relatively abundant. The latter mineral, occurring in a sandstone at Newmire, Colorado, is being commercially exploited.

Coning ore for quartering requires great care if the resultant sample is to represent a true average. Each shovelful must be dropped upon, not thrown at, the exact centre of the pile, so that it will spread out evenly in radial lines around the cone. The shovel must be dropped away from its burden to accomplish this result. Any toss to the shovelful will injure the accuracy of the sample. In shoveling-over a pile thus coned-up, it is not good practice to drive in the shovel along radial lines toward the centre, as that causes the ore to run toward such a cut and mix irregularly. The ore should be removed in progressively narrowing circles, the shoveler working round and round the pile, driving the shovel along a line tangent to an imaginary circle concentric with the base, and lying a few inches within its outer edge. Thus the angle of rest for the broken ore will be uniformly disturbed, causing the material to flow radially from the centre and so distribute itself as to yield a practically true average. The fine ore and dust remaining in the centre in too small an amount for correct partition with the shovel should be mixed and quartered on a rubber sheet, or piece of new oil-cloth, the proportionate parts being put back with the sample and reject respectively. Careless 'coning' will always give an inaccurate sample.

Cleaning mercury with ferric chloride (Fe_2Cl_6) is recommended by nearly all the textbooks, without attempt at explanation of the chemical phenomena involved. It seems improbable that any benefit would arise if the chemically pure salt were used. The commercial salt contains ferrous chloride ($FeCl_2$), and probably will generally show the presence of free hydrochloric acid, to which we would be inclined to ascribe any office of purification which may be performed. In fact, the use of hydrochloric acid itself is most commonly recommended, which is certain to be efficacious in converting lead and zinc, present as impurities, into chlorides. But ferric chloride in the presence of nascent hydrogen is converted into ferrous chloride and hydrochloric acid, thus:

$$Fe_2Cl_6 + 2H = 2FeCl_2 + 2HCl.$$

By the use of metallic sodium in connection with the ferric chloride, nascent hydrogen is rendered available by the reaction

$$Na + H_2O = H + NaOH.$$

This would seem to be an expensive method of converting the contaminating metals into chlorides, but there is a probable further advantage to be derived from the presence of ferric chloride when other metallic chlorides have been formed from the impurities in the mercury, namely, the extraordinary facility with which ferric chloride forms a double salt with other metallic chlorides. Lead chloride is difficultly soluble in water, but the double plumbi-ferric chloride is readily dissolved. Hence we have here a means of easily removing the chief impurity, which would not be so readily done without the employment of ferric chloride. The natural conclusion therefore is that the simpler and more economical and more thoroughly efficient procedure would be to treat the foul mercury with a strong solution of ferric chloride, acidulated with hydrochloric acid. We have not tried this, and information as to the result attained would be welcome.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Law.

The Editor:

Sir—I am interested to observe in your columns a renewal of the perennial discussion of the apex or extra-lateral feature of the Federal mining law. I endorse the well-stated and weighty reasons in your editorial of March 14 against the repeal of this provision. Even if the proposed 'square location' were intrinsically better, the confusion of rights and resulting inevitable litigation would far outweigh any supposed advantage.

But, in my opinion, the 'square location' would not, on the whole, be for the best interests of mining nor as nearly do justice as the present system, even if the former had been put into operation at the beginning of mining development. It seems to me justice imperatively dictates that where the miner has discovered or developed a profitable mine out of a vein or deposit, indicated usually only by uncertain and deceptive outcrops, he should reap the full reward of his courage and expenditure by having the right to follow such vein on its dip as far down as it may be profitable. He certainly has a tenfold stronger claim thereto than the surface owner, on the other side of an imaginary vertical plane through a boundary line, who has done nothing to develop the orebody. Incidental difficulties in its application should not be allowed to obscure the essential justice of the principle.

The apex provision has been a fundamental principle of our Federal mining code since 1866, and prior to that had been in existence as an essential rule of the mining customs and regulations which governed mining in the quartz or lode districts from the earliest days of gold discovery in California. This is shown by the complete collection of the rules and regulations of the old mining districts made by Clarence King for the tenth census.[1]

A large part of all law is only custom adopted either tacitly (common law) or expressly (statutory law) and enforced by the State. It is a fact in the history of jurisprudence that those laws which have thus originated in custom have generally been the ones that have given satisfaction and accomplished justice so far as any law can do this. The adoption of the customs, rules, and regulations governing mining in the early days in California and adjoining territories was a true example of the development of a 'common law.' It continued in this unorganized form for nearly twenty years before being enacted into statutory law by Congress. Is it not unreasonable to suppose that although unconstrained by any statutory law on the subject, and in a pioneer time when all social and business institutions were in a particularly plastic and unsettled condition, these adventurous and untrammeled miners would have adopted in all districts this principle to regulate their property rights, and have maintained the same for nearly two decades and finally asked and secured through their representatives in Congress its enactment into a statute, if it were not the best rule for existing conditions?

But has the advance of geological knowledge concerning veins and ore deposits or the enormous modern extension of mining operations rendered the apex law unsuitable for our own times? I do not believe so. During 1907 a discussion was carried on in *Economic Geology* on the topic 'Do the geological relations of ore deposits justify the retention of the law of the apex?' in which Chester W. Purington, Courtenay De Kalb, and other prominent mining men took part and adduced the specific geological instances in which they claimed the apex law worked injustice. It is to be presumed that they presented the strongest examples they knew, and their standing makes it extremely probable that their knowledge included all important objections.

In a contribution to this discussion[2] I have analyzed these instances and have shown, as I believe, that in each case the objection was not valid, being based either on fallacious reasoning on the assumed geological facts or on a misunderstanding of what the law really is applying to said assumed facts. Mr. Purington, in particular, has been especially hostile toward the apex law, but although a year has elapsed he has allowed my arguments to stand unanswered. The other participants have done the same. This, of course, does not prove that the said arguments are unanswerable, but I believe that if they had seemed vulnerable, they would not have remained so long unchallenged.

I only mention this because, from lack of space, it is impossible to cite and discuss such instances in detail here, but it is on such concrete examples that our general judgment of the desirability of the apex law must be founded, rather than on the casual suggestions or unsupported assertions of men untrained in jurisprudence. Consequently, it seems to me, not only do the weighty considerations of the confusion and unsettling of existing rights, etc., stand against changing the long established policy of the mining law with regard to apex or extra-lateral rights, but also the more fundamental considerations of adaptation of the law to secure the largest possible measure of justice, both in pioneer times and under modern conditions, are likewise opposed to change in that respect. I think that if Mr. Tays attempts to furnish concrete instances of the "absurdity" of the apex law's operation, he can do no better than Mr. Purington *et al.* Mr. Turner seems to think it an argument against the apex law that placers are located under a 'square location' provision, but this argument is entirely fallacious, for the geological conditions in a placer deposit are entirely different from those in a vein or lode deposit. In regard to the Leadville cases, it was not because "confusion worse confounded would have resulted from its application" that the apex law was, in effect, nullified, for that locality, by the uniform decisions of the juries that the blanket deposit there found extending under different claims, was not the same vein in the

[1] Report Tenth Census, Vol. XIV, 'Mining Law.'

[2] *Economic Geology*, Vol. II, p. 62.

different claims, although scientific opinion was otherwise, but because of the intense local feeling against allowing the outcrop locators to monopolize the extensive deposits that could be readily reached by shallow shafts from the surface in other claims. The like has often happened to other excellent laws. For example, the State law for Sunday-closing of saloons is absolutely nullified in Chicago because no jury (which the violators have a right to demand in every case) can be secured that will convict, on account of local sentiment against Sunday-closing laws.

It is admitted that the provisions of the apex feature of our Federal mining law are rather vague and left many points uncertain, but this was inevitable in the primitive conditions of geological knowledge and mining development then existing. This indefiniteness, however, has been removed by the decisions of the courts during the period of over forty years since its enactment. By a kind of judicial lawmaking, consisting of the application of the necessarily general provisions of the statutes to the concrete facts and relations of the real cases, a definite and sufficiently elaborate set of legal rules have been evolved to meet practically every contingency in mining operations.[3] Of course, the difficulty still remains in each case of ascertaining what the geological facts are in relation to a given mine, but the same exists in all legal disputes, particularly those involving technical and scientific subjects. It has unfortunately cost considerable expensive litigation to accomplish this, and to that extent the critics are justified in their strictures, but it was simply impossible that it should be otherwise, for the complexities of veins and other forms of ore deposits could not possibly have been foreseen when the law was enacted.

I seriously doubt the advisability, at this late date, of attempting to modify the present law in any particular, although with our present knowledge of ore deposits, if the law were now first proposed, I would advise an attempt to define and exclude 'blanket' deposits, and also fix the status of ancient buried placers, which is still uncertain by reason of conflicting decisions thereon by the lower courts. The entire repeal of the apex or extra-lateral principle would, I believe, be a positive misfortune to our mining industry.

Springfield, Illinois, April 28.

Separation of Slime.

The Editor:

Sir—The article in your last issue by Horace G. Nichols on 'The Separation of Slime in Cyanide Treatment' is of great interest to millmen generally. The devices used will not only simplify and reduce costs of cyanide treatment, but they will give to millmen a reliable and efficient de-watering device.

In the fall of 1906, while building a concentrating mill in a region where water was scarce, I had occasion to look up the various water-saving devices. None that were submitted promised to be satisfactory, and the best results obtained were said to be the treatment of one ton of ore with a loss of half a ton of water. I then designed, but did not build, a device very much like Mr. Nichols' tank, through which a conveyor belt was to run for the purpose of removing the final tailing from our concentrator. I did not expect, however, to secure such results as Mr. Nichols has obtained: the removal of 94.97% of the tailing with a loss of 31.3% water, and all of the tailing with a loss of 36.07% water. In this case there was a large percentage of slime, much greater than there would be where the ore is not treated by cyanide. The concentrating plant I was building was designed to make but a small percentage of slime, less than 10%. This mill has not yet been completed. In view of the facts, it would seem that Mr. Nichols' device is the best dewatering scheme available, as it is safe to figure that by its use a ton of ore can be crushed and concentrated with a loss of but 500 lb. water.

Gasoline Connections for Assay Furnace.

The Editor:

Sir—As a means for conducting gasoline to an assay furnace, I beg to describe a method which is original so far as I know. I made use of a 20-ft. length of hollow wire, or tube, of copper alloy, ⅛ in. diam. on the outside. At each end was placed a combination ¼-in. valve and union. One valve was placed directly on top of the pressure tank, the plug being tapped to receive it, and the other valve screwed into a short piece of ¼-in. pipe, using a sleeve-coupling. This piece of pipe, about 1½ ft. long, led to the burner. The gland nut being placed on the wire, the glands were silver-soldered at each end. This obviates all risk of the solder melting, especially at the burner connection. For a pressure tank I made use of an 18-gal. water cylinder, tapping out the water and air plugs for ¼-in. pipe connections. A piece of cotton wicking was inserted at the upper end of the ⅜-in. pipe inside of the tank to serve as a filter for the gasoline before going through the wire. This scheme possesses the following good points. It has no leaky joints, is easily set up or taken apart, is not as heavy and cumbersome as the usual ¼-in. pipe-connections, and there is less chance of spilling gasoline in case of accident to any part of fittings outside of the pressure-tank. The hollow wire employed is that used so extensively in gasoline lighting, and can be purchased anywhere.

HERBERT W. CUMING.

Victor, Colorado, April 24.

Mine-Fires.

The Editor:

Sir—In your issue of March 28, W. O. Snelling proposes the use of sulphur dioxide as a means of fighting mine-fires.

There are some cases where this might be of no avail, as the gas is a supporter of combustion itself in the sense that it is reduced by incandescent carbon. This reaction is the basis of the original patents of Schroeder and Haenish for the recovery of

[3] See chapters XIII and XIV of my book 'Mining, Mineral and Geological Law' for a statement of the rules resulting from an analysis of the decisions on the apex or extra-lateral law.

sulphur from furnace-gases. It is also employed in my own processes, while Paul I. Smith makes use of water-gas. In other words, incandescent carbon from burning mine-timbers will continue to burn in an atmosphere of sulphur dioxide, and the reduced sulphur might 'burn' in some other part of the mine, thus prolonging the trouble indefinitely.

FRANKLIN R. CARPENTER.

Denver, April 14.

The Mining & Metallurgical Society of America.

The Editor:

Sir—The comments on the charter and by-laws of the new society appearing in your issue of May 2 are quite likely to be misunderstood by those not intimately conversant with the aims and objects of the Society and the relation of these to the American Institute of Mining Engineers. The statement, "let the Institute work the lode that it located, patented, and developed thirty years ago," may perhaps better be understood by reference to the location notice posted in May, 1873, which reads:

"The objects of the American Institute of Mining Engineers are to promote the Arts and Sciences connected with the economical production of the useful minerals and metals, and the welfare of those employed in these industries, **by means of** meetings for social intercouse, and the reading and discussion of professional papers, and to circulate, by means of publications among its members and associates, the information thus obtained."

While opportunities to amend this certificate were afforded in 1875, '77, '78, '80, '81, '87, '90, '96, 1903, and 1904, when the Rules governing the business of the Institute were amended, this original notice remained unchanged and became the final certificate of location, as stated in its Certificate of Incorporation finally adopted in this form February 21, 1905. The tendencies of the rules and amendments adopted from time to time have been to construe this statement of objects literally, i.e., to restrict the activities of the Institute to the **reading, discussion, and publication of professional papers**; to limit, rather than to expand, its functions, so that by thirty-five years of practice and precedent the extent of its territory is now well defined. In other words, it has disavowed all claims to "dips, spurs, angles, cross-veins," etc., confining itself strictly to the one lode, and to that within definite boundaries.

Hence the adoption by the new society as one of its objects, "the increase of scientific knowledge," does not imply trespass upon territory to which the Institute has acquired exclusive rights; for there are many ways of increasing scientific knowledge other than by the publication of professional papers; and further, the Institute has for many years permitted others to enter its territory and to work its ground as tenants in common.

The clause above quoted will enable the Society, if it so desires, to **encourage original research** (it was in fact substituted for these words); to embark upon the **collation, condensation, and classification** of useful data, in tabular, periodic, or encyclopaedic forms; to **conduct investigations** through committees appointed for that purpose; to **offer premiums, medals,** etc., to stimulate and reward scientific discoveries; and to assist in securing scientific work by or through governmental agencies or support.

In some or all of these directions the Society should become a useful and valuable organization without duplicating any function which the Institute has heretofore performed.

If the Institute actually control the publication of all technical articles connected with the mining and metallurgical industries, a valid objection to the new society would be that it might invade this field; but the field is already divided, for other scientific societies and the technical journals and periodicals obtain many professional papers that should go to the Institute if the Transactions of the latter are to embrace all literature of this kind. As a matter of fact, the annual publications of the Institute embrace but a small fractional part of current American mining and metallurgical literature. In this connection it may be interesting to note the effects of the growth of the Institute, and of the industries and population of the country, upon its work. In 1875-77, with 400 to 500 members, its publications annually comprised 500 to 600 pages; in 1890-92, with 2000 members, representing industries which had tripled in value of output, its Transactions embraced about 1000 pages, and in 1906-07, with 4000 members, representing enormously enlarged industries, its Transactions include about 1100 pages of technical matter. It is, therefore, evident that while the Institute has grown in membership somewhat in keeping with the growth of the population and industries of the country, its publications have kept pace neither with the number nor with the activities of its members. In other words, its importance as a bureau for the publication of technical papers has relatively diminished, the field having been invaded by local and specialized organizations of technical workers, and by the increased number and enterprise of technical journals and periodicals. If the Institute is to retain its prestige in this field, it must be prepared to meet the competition of the technical journals and of technical societies such as the Chemical Society, the Electro-Chemical Society, the new American Iron & Steel Institute, the Canadian Institution, the Coal Mining Institute of America, and many local engineering and scientific organizations. It need not fear active rivalry from the Mining & Metallurgical Society of America.

H. M. CHANCE.

Philadelphia, May 8.

A Matter of Ethics.

The Editor:

Sir—Your very interesting discussion of the Yukon Gold flotation leads me to request through your columns an answer to a question of professional ethics. It is currently reported that while Lawson was making a market for the Yukon Gold stock, Mr. O. B. Perry and some of his associates sold some of their shares in that company to the public. My question is this: At a time when the report of a mining engineer is being invoked by his employers to establish

a certain market valuation for a mine, is he justified in throwing his own shares in that mine on the market? He sees his report used to convince the public that the mine is a good buy at a certain price, and he does not publicly protest against such a use of it. But by his actions he seems to say that the mine is a good sell at that price. Is it right for him to be acting on both sides of the market at the same time?

SOCRATES.

San Francisco, April 28.

[This is a delicate question. We are not sure that even 'Socrates' has all the facts. If the engineer was not consulted as to the transaction in which stock was optioned to a promoter, and if the stock was placed on the market at a price two or three times the valuation warranted by the engineer's own report, it seems logical for him to sell, and thereby warn the public. If it is proper to buy shares in the mine on which you report, it is also proper to sell when the price becomes highly speculative. We are not aware that in this case the engineer was acting "on both sides of the market": it will probably be found that he was not a party to the attempt to create a market at a fictitious price and if he thought the shares were not worth $7.50 to $9, he was perfectly logical in selling stock that he probably got at $3. If mining companies encourage their engineers to buy stock, they are estopped from complaining against the selling of that same stock whenever the price becomes inflated.—EDITOR.]

Value of Mining Stock.

The Editor:

Sir—The question discussed by Mr. M. L. Requa in a recent issue regarding the measures necessary to clothe mining stocks in a garb that will commend them to the eye of a banker as collateral, is one that deserves a practical solution. History has indeed invested these mining stocks with a character not calculated to encourage intimate acquaintance, and if any method can be devised by which they may hope to make a better showing, that method would certainly be most welcome to business men who have regard for decent appearances. It is not only, as Mr. Requa indicates, a matter of satisfying a banker's requirements for a collateral, but also the broader question of commending such securities to the investor with something more than the embellishments of printer's ink.

Before suggesting any means whereby improvement may be effected it will be necessary to analyze in some degree the conditions under which mining stocks in general come into being. In this aspect it will be found that they bear too close a resemblance to the human family to warrant the hope that there will ever be such general and universal amelioration as to impart a uniform character of moral and physical perfection to them. This is not apparently what Mr. Requa anticipates, but what he would like to see is some modification of the bankers' attitude, which excludes all mining stock from the list of acceptable collaterals. And in this connection he sees another deplorable fact in that "not one of the great mines of the West is controlled in San Francisco," which might indicate that there is not one capable and honest man in San Francisco, or if ever there was one born and brought up in that city he was captured and taken away to New York or London!

While rightly claiming the normal process of evolution in the development of mines from prospects, Mr. Requa seems to regard as necessary to the rudimentary stage "excitements, booms, stampedes" and "wild-cats," but regards as unfortunate the fact that the "first period is merged into the second," that is, in the opinion of the public, which fails to differentiate between the multitude of wild-cats and the thoroughly proved mines. It may fairly be questioned on logical grounds, whether such differentiation is to be expected, or even whether it is justified by the facts. Unfortunately, tendencies abide, and what are born as 'wild-cats' mature, if they mature at all, as manipulated stocks of developed mines.

This classing of 'wild-cats' and 'prospects' as necessary correlatives in mining, may be the prenatal influence that determines the after conditions which Mr. Requa rightly deplores. Is it not the wild-cat nature that has for many years directed the policy of mine promotion in San Francisco? That unfortunate city has had to bear the stigma of many evils, which in its regeneration it is striving manfully to cast off, and if this wild-cat evil, along with other evils, can by any means be discarded, it will be a consummation devoutly to be wished. But is it consistent to absorb fool money for prospect mining, and then solicit wise money for the developed mine? Is it rational to expect anyone to differentiate between the period of rascality and the period of honesty in the growth of a mine?

Will "systematic reports" remedy the evil? Is it not the absence of confidence in the methods pursued throughout the entire career of mine creation and activity, rather than the want of "reports," that operates most severely against the acceptance of mining stocks by bankers and sane investors? A systematic method of reporting to stockholders regarding the affairs of a mining corporation is certainly a crying need: and not only so, but methods should also be devised whereby such reports could be received with the practical assurance of accuracy. Publicity would seem to be the least requirement to be expected from such corporations as subsist on public subscription, and in its application, mining corporations may well be included with those of banks and railroads. Under present conditions it is doubtless true, as Mr. Requa states, that such reports would probably act as a boomerang. Doubtless the Stock Exchange might render valuable service to the cause of legitimate mining, but here again it would appear that measures of reform are in order.

As before indicated, some sort of classification of mining stock appears necessary, and that along pretty well defined lines, in order to arrive at a comprehensive understanding of the situation. The question of qualifying mining stocks for use as a bank collateral by creating conditions necessary for their production, remains to be definitely answered.

Mr. Requa names concisely the necessary characteristics of such stocks, and answers the question whether it is possible to meet the tests by an emphatic "Yes," and follows up his affirmation by designating three conditions which, if fulfilled, would solve the problem.

Permit me to ask, would Mr. Requa himself travel the road he indicates? Can a mine-owner be found who will consent to a capitalization of his property, based on the findings of the tape-measure, the assay-office, and the cost-sheet? I doubt it. Not that I question Mr. Requa's sincerity, but because I think he goes beyond what in practice might be fairly considered as just to himself. I think he concedes too much to the demands of the banker. Not that I desire to weaken the banker's security, but I doubt, even if all were granted that Mr. Requa is willing to concede, whether the banker would be quite satisfied. I humbly express the opinion that the desired end, if it can be reached at all, must be reached by some other route. The situation appears to require that an organization be formed which will undertake to create the necessary conditions for imparting to an issue of mining stock those elements of reliability and stability which will bear scrutiny, both for investment and for collateral purposes. This must be undertaken with a thorough understanding of the peculiar conditions that are inseparable from mining, in contrast to any other industry or financial institution. In a word, it is a question of adapting a financial scheme to the exceptional requirements of legitimate mining, in which the public is to be interested.

The ideal conditions under which mining is conducted are those in which a corporation, composed of half a dozen men, or less, has all the capital it requires without borrowing, has its own mines, large and rich, and goes ahead and extracts the mineral from the earth in its own way, and keeps its knowledge to itself.

While there may be a few corporations thus happily situated, the majority of mining companies, even of the reputable class, must deal with the public, and this is certainly a proper field in which to operate, and to achieve success on legitimate lines, but it must not be forgotten, as Mr. Requa points out, that differentiation is necessary in determining the relative merits of mining stocks, and in order to facilitate that process the following classification is offered in a suggestive spirit:

1. Wild-cat—Numerous, deadly, cannot be killed, to be avoided.

2. Prospect—Speculative; if successful, profitable. Not suited to public subscription.

3. Listed Producers—Subject to manipulation, or closely held. For investment purposes, difficult to discern good from bad. If good, rarely obtainable.

4. Unlisted Producers—Held by close corporations. Highly developed. Inaccessible to public.

5. Investment Producers—Operated under central management. Successful if in the hands of capable and honest men. Safe, if properly financed. Best adapted for public participation. Very rare.

Berkeley, April 23. INVESTOR.

AN ACID-RESISTING ALLOY.

According to a paper by A. Jouve, presented at a recent meeting of the *Société des Engénieurs Civils de France*, the chemical industry is to benefit materially by recent advances in the study of alloys of iron and silicon. The great difficulty in the manufacture and concentration of acids has been the lack of a satisfactory material for the construction of the vessels in which they are produced. Recent investigations, of which the following abstract of M. Jouve's paper gives a brief outline, have revealed in certain metallic compounds in which iron and silicon are the predominating elements, a combination of properties which apparently will remove the most troublesome and costly features of acid manufacture.

The ordinary materials used, such as glass, porcelain, and stoneware, are both fragile and limited as to possible size. Alloys of platinum and iridium, or platinum and gold are used, but their cost is high, and the consumption of platinum by the acid increases rapidly with the degree of concentration. Lead cannot be used for concentration above 60°B, and cast iron is attacked by dilute acid.

The researches of M. Jouve were based on a laboratory observation of the difficulty of dissolving iron-silicon alloys in acids, a difficulty increasing with the percentage of silicon. The acid-resisting properties of these alloys immediately suggested their utilization for the construction of appliances for acid manufacture. The alloys experimented with were complex metallic silicides of high silicon-content, in which the silicides of iron formed the principal part of the mixture. After a compound with the necessary acid-resisting qualities had been produced, great difficulties were met in giving it qualities by which it could be cast in desired forms, particularly when handled in large masses. This was accomplished by the addition of certain other substances to the compound of iron and silicon. M. Jouve does not say what these substances are, that remaining a trade secret. Their use, however, produces a metal which fuses readily and takes the mould perfectly. The product is in successful use in the concentration of sulphuric acid and in the condensation of nitric acid vapors, in France and other European countries.

Volcanoes standing in such perfect alignment as to indicate that they constitute vents along a straight dike or fissure are rarely found in any considerable number, hence the report of Henry G. Ferguson in the Philippine Journal of Science for February on the 'Physiography of the Batanes Islands,' is of great importance. The following vents, many being active, with their corresponding longitudes, constitute a truly remarkable ease: Y'Ami, lon. 121° 58′; Mabudis, 121° 57′; Inem, 121° 57′; Iraya, 122° 01′; Balintank Rocks, 122° 08′; Babuyan Claro, 121° 56′; Camiguin, 121° 52′; Didicas, 122° 09′; and Cagua, in northeastern Luzon, 122° 04′. The author remarks that this close alignment of the volcanoes of the Babuyanes and Batanes groups, and the supposed fault between Sabtan and Ibujos, suggest the existence of a great north and south fissure, and he reverts to the theory of oceanic stimulation of volcanic activity.

MR. MURPHY ON THE NEW SOCIETY.

Written for the MINING AND SCIENTIFIC PRESS
By An Occasional Contributor.

(*With apologies to everybody.*)

"I see be th' pap'rs," said McCarthy, as the shift-boss disappeared down the next man-way, "that they do be formin a new sassiety f'r mining injineers."

"Yis, I saw it, too," answered Murphy, as he sat down on a candle-box to light his pipe.

"What do it be all about, do ye moind?"

"Well, I'll tell ye how it looks to me," said Murphy. "There's a la-ad back in Philadelphy by th' name iv Chanee, who's belonged to me frind Ross Raymond's sassiety so long he f'rgot whin he jined: an' one day whin th' byes was a little slow about bringin' in pieees iv slate soaked in our Uncle Jawn D's extry water white, an' payin' money f'r him to tell thim that while it wud burn, it was no good, he got t' thinkin about how Rossiter had niver ast him t' be prisidint 'r sicritary 'r nothin iv his sassiety, and he got in a foine frinzy.

"So he made him a little dummy stuffed with hay, an' with white side whiskers an' glasses, an' thin gave it a bat alongside th' head that knocked it as fur as yon stull, an' says, 'Why don't ye do somethin worth while, instid iv dodderin around with ye-er books?' he says. 'Why don't ye assay th' ore iv th' poor'r prospeckter, and deeskiver anither Tonopah?' he says. 'Why don't ye boss th' govermint more, an' make Tiddy tell Jo Cannon what t' do?' he says. 'Why don't ye git busy like me frind Ralph Pope on th' nixt flure t' ye, who has his elictrical sassiety diskussin' ithics, an' actin like me deer Alfonso an' me deer Gaston till ye can't rist?' says he. 'Why don't yet git afther thim fellies out in Nevay-dy who're coaxin good money out iv th' peeple that we ought t' be gittin?' he says. 'Why don't ye have min in ye-er sassiety that amount t' somethin, anyhow?'' says he. 'Sha-a-me on ye!' he says.

"An' thin he gits out his book iv mimbers iv th' Ameriean Institoot, an' runs his finger down th' list iv names, an' picks out a bunch iv fellies like himsilf, an' says he will firm a sassiety that will mane somethin, an' he invites thim all t' be charther mimbers.

"He sinds word t' thim too iditor la-ads Ingalls an' Rickard, that they're invited t' jine, f'r fear they'll be afther knockin his sassiety in their pap'rs, if he don't, but they're hard la-ads t' handle. Th' la'ad Ingalls raytires t' th' sayelushun iv his idaytorial sa-angtum, which has all th' daystinekshun an' individoolity iv me locker in th' dry, an' writes a foine sareastic arthiele abont th' new sassiety, an' thin takes it in an' shows it t' his boss Hill, t' see if he will stand f'r it. Hill looks up th' la-ad Chanee in his eard index, an' foinds that he earries an advertismint in wan iv his pap'rs, an' subscribes f'r anither, so he takes his blue pincil an' mar-rks up th' arthiele till ye wouldn't know it.

"Th' la-ad Rickard, though, is his own boss, or says he is, an' he goes jumpin an' barkin at th' new sassiety like a pup at a sthranger intherin th' yard. He's a strong hand with a pincil, an' slings English loike it was his mither's tongue, instid iv th' lingo thim Cousin Jacks do be talkin, and he's a hard wan t' make shut up.

"But th' la-ads all git t'gither finally, an' e'ngrathulate aich ither on bein' charther mimbers iv th' grate new sassiety they ar' t' form, an' they dhraw up a constitooshun an' byelaws. They make officers out iv th' iditor chaps, so they will kape quiet, an' stop their knockin.

"They sind a committy t' see me frind Ross Raymond, so as t' fix it all up an' be good frinds, an' print their stuff f'r nawthin. But th' old bye is wise t' their game, an' shows thim out th' back dure.

"So they says t' thimsilves: 'We'll take out a pat'nt on a new brand iv ithics, that nobody ilse can use without our sayso'."

"What is this ithies they do be talkin about?" interrupted McCarthy.

"Well, I can't exaetly tell ye what it is," said Murphy, "but I'll try t' tell ye what it does. Suppose ye do be sittin in a little frindly game, an' ye think ye have dilt th' ither la-ads three eards aich that are aloike, an' ye find t' ye'er surprise that ye have a full hand ye'ersilf, it's ithics that fills ye with foine noble sintimints, an' restrains ye-er hand f'rm its deed iv slaughter, whin a frind signs ye that thrn a mistake wan iv th' other la-ads has foor iv a kind.

"Well, these la-ads that are formin th' new sassiety throws out the'r chists an' says in th' pap'rs t' th' la-ads that are scatthered over th' country too busy runnin th' mines t' pay much attenshun t' what is goin on: 'If ye are not mimbers iv our sassiety,' they says, 'ye are no good,' they says, 'an' we don't intind t' let ye jine,' they says."

"Is Tom Lawson a mimber?" said McCarthy.

"I dunno, but if he ain't he ought t' be. He has been th' subjeck iv more ithieal diskussions in th' past tin years thin annywan I know iv."

Gold in Hungary has been produced by native diggers on the banks of the river Drau for several hundred years, and at the present time, according to an account by A. von Gernet, in the Bull. I. M. & M., there are some 200 men earning their living at this work, which is being performed by most primitive methods, with an average yield of from 2s. to 3s. per day per man. Recently, a firm in Vienna obtained the right to exploit the gold-bearing gravel for a distanee of 25 miles between Zakany and Visvar. The river is shallow, wide, and rapid, and consists of several channels having a maximum depth of 10 ft., forming a number of islands. The surrounding country for a width of from one to two miles, as well as the islands and the river bed, are of gravel, and at certain seasons are covered by from 3 to 5 ft. of water. At such times the stream flows about 4 ft. per second, and changes the aspect of the river by forming new islands and channels. The gravel generally is 25 ft. deep and rests on a bed of clay. The upper 6 in. of gravel frequently carries from 1s. to 1s. 6d. per ton, the value diminishing in depth until at 2 or 3 ft. it is only 1d. or 2d. per ton. It is of interest to note that rich places, after being worked out, become enriched again at the flood, a phenomenon common in some auriferous streams.

MEXICAN NOTES.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

The accompanying photographs will serve to present a contrast between the old and the new arrangement of treatment-plants in Mexico. The great majority of mines now in operation in Mexico are old, and are under American management. Americans having taken abandoned mines and those that have been presumably worked unsuccessfully by others.

Fig. 1. In the Patio.

Modern methods and machinery are doing their part in the development of Mexico, but even an American manager cannot make some mines profitable. In estimating the value of some of the larger mines a few years ago, when silver was high, the engineers supposed themselves perfectly safe in estimating silver at 65c. per oz. Today's quotation is 53c., with a drooping tendency. In Mexico City one hears almost nothing in hotel lobby club but such remarks as:

"Mexico must be put on a silver basis again or the nation will be bankrupt."

"Silver is the main support of the Government, and what will the latter do when mines and mills close down?"

"India will soon resume coinage of silver and the price will go up."

"China's buying will raise the price."

"The present supply of silver is not equal to the demand."

The same remarks, with variations, were made when silver dropped in the United States, and with about the same proportion of truth and error. Silver is produced now at a lower cost than ever before. MacDonald gives the cost of the tedious patio process as ranging around $25 when a Mexican dollar was equal to a gold dollar. Treatment took such a length of time, sometimes more than a month in the patio alone, that the crushing department was small and insignificant compared to the area required for amalgamation. At the present time, when the cost of everything used is higher, including mules, men, fodder, and corn, the patio would absorb even a larger proportion of the ore-value than does the smelter, with no one the better off for it. At Guanajuato and Pachuca, where the process flourished, the site for a *hacienda* generally consisted of the steep side or wall of a gulch, part of which had to be leveled off to prepare the extensive yard or patio. When a cyanide plant is built in the *hacienda* where the *torta* underwent amalgamation, this extensive paved area serves excellently as a site for leaching and agitation-vats. Such a prepared floor is shown in Fig. 1. No more work than necessary is done in preparing the old

Fig. 6. Rurales on Dress Parade.

hacienda for the new plant, and so we find steel vats and electric motors surrounded by thick high stone and adobe walls (Fig. 2 and 3), which serve no better

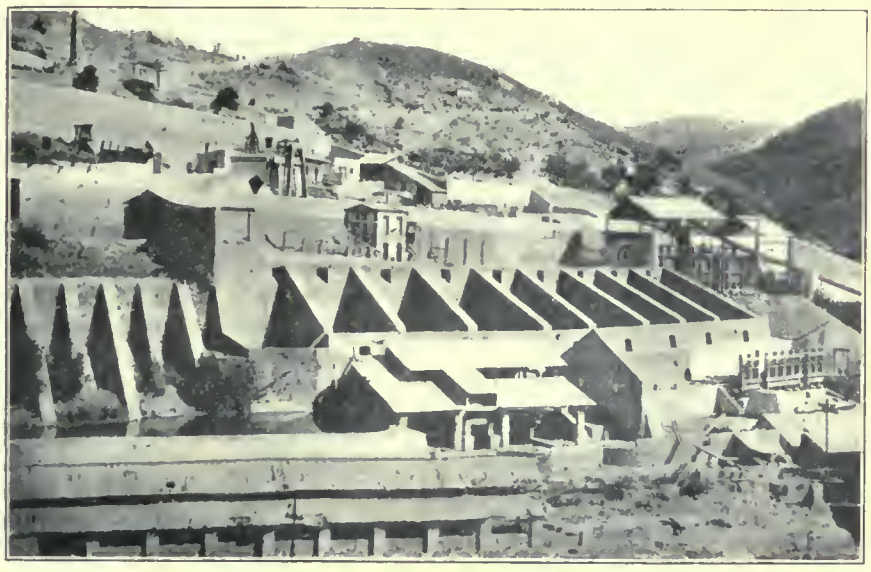

Fig. 3. Ore-bins and Stamp Mill.

than a wire fence in these days of peace and security. However, in many places in Mexico, where labor is cheap and freights are high, it is cheaper to build a stone wall than a wire fence. In Guanajuato good masonry costs about $1.6 per cubic metre, a stone wall built with mud instead of lime mortar is cheaper, while an all-adobe costs less. These walls and their corner lookouts (No. 4 and 5) are provided with narrow rifle-slots which served well in defending the *hacienda* from the assaults of bandits. In one old *hacienda* are still standing at frequent intervals

Fig. 5. The High Noria.

Fig. 4. Ancient Aqueduct.

around the grounds, two-story square towers with radial slots through the walls. An old water-carrier, who thirty years ago was a guard, tells thrilling tales of assaults from without and of robbery from within. "Ah, Señor," he said, "you should have seen the guards who were occasionally caught assisting the *bandidos*!" He smiled at the pleasantly exciting recollection. "They were lined up against the wall and given their just dues. Several times have I been distinguished by being singled out of the firing squad to give the *tiro de gracia* (the final shot), given when some of the squad have been awkward or nervous, due perhaps to having a relative to shoot!"

Sometimes there was a second guard to watch the watchmen. This second *velador* wandered armed through all the plant, watching the guard and the workmen closely. It was a difficult berth, as in case of an assault from without, he was an easy mark for any peevish guard in a tower. "The *patron* was certainly master in those days," the old carrier went on. "Do you suppose he would condescend to converse with a common *peon* such as I, as you are doing?" he asked, watching me scornfully out of the tail of his eye. "*Peones* are to be given orders and are to work, but are not to be associated with." He adjusted the strap of his large *cantero* (clay water-bottle) over his forehead and complainingly lifted it. "In the old days I received 20 centavos for a bottle of water at the *hacienda*. Now, with these *malditos* water-pipes on every corner I rarely receive 4 centavos. Why," as a parting shot, "if it were not for the crazy Americans who pay me 10 pesos for these

bottles which cost me one peso with all and harness, I would be really poor!" This last he said after he had bitten the coin I had given him for his information! One of the little watchman's towers was pointed out to me by an old inhabitant of a deserted mine as still containing bombs and hand-grenades. We could see these through the rifle-slots and with little persuasion the old fellow produced pick and shovel, with which we dug away the fallen wall which obstructed the entrance. The bombs were there in piles—made of quicksilver flasks, sections of pipe, thick clay vessels, and special castings, some loaded and some empty. The fuses looked a little too old for safety, so in several of the bombs the old fuse was replaced by a new one, which was lighted. The effect was sufficient to inspire profound respect. We judged that the result of their use in times past must have amply repaid the expense. It requires little time to find big lead bullets in the walls near these port-holes, and I chose to believe that they were the original messengers from envious anarchists of the last century—anarchists until President Diaz disciplined them. These former terrors of Mexico, since re-enforced by younger blood, now play the part of rural guardians of the peace—*rurales*. They are guardians, moreover, whom it is best to treat with the utmost consideration and attention when they most respectfully request information as to your business and destination, along the highway. This is particularly true if you are evading regulations, such for instance as carrying arms without a permit from the police chief of the district when this is required. The story is told that a few years past, when bandits became temporarily bold, a chief of *rurales* was sent to this district with men and instructions to clean out the outlaws, who were attacking the bullion-trains.. This gentleman was thrown on his own resources. Results were wanted, and he had to find the method. His men were posted on the various roads and arrested suspicious characters, bringing them before the chief. He himself, meeting a suspicious *peon* on the road, might question him as follows:

"What is your name and for whom do you work?"

"Señor, I am Juan Soto. I am *vaquero* for Don Luis."

"*Vaquero*, eh? Let me see where the horse-back riding has callousd your legs."

The *peon* exhibits his bare legs, which have never known a pair of pants, and if the signs are right he goes on his way safely. If not, a revolver shot made one less bandit—probably. And what of an occasional mistake? Such a process would do wonders in certain parts of our most civilized United States. With this story in mind it can be easily believed that the bandits soon became discouraged. The *rurales* make an efficient police. On dress parade (Fig. 5) the leather of the saddles and bridles appears to be merely a foundation for a superstructure of silver. Immaculate tall white Mexican hats covered with silver, tight leather pants, and short leather coats similarly covered with silver, make a costume which is not ungainly and with which no other uniform in America can be compared for beauty.

PREVENTION OF RUSTING.

The scientific reasons for rusting, and the conditions under which it occurs, are well set forth by W. H. Walker in the *Iron and Coal Trades Review*. He says, when a plate of iron is immersed in water positive and negative areas of greater or less extent relatively are developed. It is possible to conceive two cases as occurring among all the possible arrangements of positive and negative areas. The first case would be that of a positive spot surrounded by an extended negative area, and the second would be of a negative spot surrounded by an extended positive area. At the positive areas iron will pass into solution and rapidly oxidize to the loose colloidal ferric hydroxide and oxide which are known to migrate, under the influence of electrolytic action, to the negative poles. In the progress of the rusting under water it would be expected that in the first case the ferric hydroxide would be piled up in a crater with the metal eaten away at the centre, while in the second case the hydroxide would form in a conical mass with the surrounding metal eaten away. These two formations do occur on every sheet of iron that has rusted under the water. According to the electrolytic theory, all substances in solution which contain hydrogen ions should stimulate the rusting of iron, and all substances which develop hydroxyl ions to a certain extent inhibit rusting, and, if the concentration be sufficient, absolutely prohibit it. This application of the theory is borne out by the behavior of acids, salts of strong acids, and weak bases (which hydrolyze in solution or decompose to an acid reaction), and by the alkalis or salts of strong bases with weak acids.

It has been long known that solutions of chromic acid and potassium bichromate retard the rusting of iron. Experiments have shown that iron immersed in a $^1/_{640}$ normal or stronger solution of the latter will not rust. It has been observed, too, that if a rod of bright iron or steel is immersed for a few hours in a 5 or 10% solution of potassium bichromate, and removed, thoroughly washed and wiped, and then immersed in water, rusting is prevented for a length of time averaging from a few hours to weeks. Cushman explains the effect as one of polarization produced by the separation of oxygen from the solution and its retention on the surface of the metal in some way without the formation of an oxide. If, as the electrolytic theory assumes, rusting is due primarily to the exchange of hydrogen ions, iron in the condition of an electrode, polarized with oxygen, should be protected from electrolytic action for a greater or less time, depending on the amount of polarization. There is little doubt that all conditions which interfere with electro-chemical action also inhibit rusting of iron, which fact in itself argues for the electrolytic theory.

Traces of moisture in such fluids as alcohol, ether, and so forth, may be detected by the use of colorless potassium lead iodide. If water be present in the minutest traces it will decompose the double iodide into its components, the lead iodide giving to the liquid an intense yellow color.

WATERS, METEORIC AND MAGMATIC.

Written for the MINING AND SCIENTIFIC PRESS
By JAMES F. KEMP.

In several relations of national importance the subject of water has in recent years assumed prominence. The reclamation of arid lands in the western portion of the country has led the Federal Government into enterprises of far-reaching consequence. Many officials are now engaged in recording and tabulating observations of the amount of rainfall and of the possibilities of storage in favorable localities. Even the divides of well-established lines of drainage are no longer safe from tunnels; and streams of no small size are either now flowing, or soon will be, regardless of geological or physiographical barriers. In the central portion of the country, the region of the great plains, artesian supplies have been especially sought and the drill has explored the depths, oftentimes yielding water, always adding to our stratigraphical knowledge. Underground reservoirs have furnished supplies in places far removed from the obvious catchment basin and the stream has been known to emerge under such head as to run a turbine upside-down. Our usual experience has been as much reversed as it was by Stockton in his droll story of 'Negative Gravity,' whose hero invented a machine that in adjustable degrees destroyed for its possessor the all-persuasive attraction of Mother Earth.

In the East the rapid growth of greatly concentrated population has made the questions of water supply of most insistent importance. As an example, New York City alone is busily and somewhat anxiously pushing the construction of a great aqueduct and reservoir, whose final cost will doubtless reach the estimates of $160,000,000. Every stream in this older settled part of the country has been gauged and its possible supplies have been measured and recorded in the same way in which we calculate our reserves of coal, iron ore, or other solid minerals. Water has become a great national asset. Nor can we eliminate it from the field of morals as we see the prohibition movement spreading from State to State. The water-wagon of the jester has become the band-wagon, if not the triumphal chariot, of the reformer.

In the discussions regarding the origin of ore deposits which have been vigorously and fruitfully maintained within recent years, underground waters have naturally been a leading topic. Views have undergone very interesting development and have at length attained the possibilities of quite definite statement. A condensed summary of past conceptions and of recent modifications may be of interest not alone to the general reader but also to those actively in touch with the phenomena of veins.

There are two kinds of underground waters with regard to origin and they are usually called in English the 'meteoric' and 'magmatic'. Abroad, the name 'juvenile', following the suggestion of Edouard Suess, the Vienna geologist, is sometimes used for 'magmatic' and we occasionally see the same application in English, but with us 'juvenile' is so firmly established in a different sense that it is very badly chosen and 'magmatic' is much to be preferred. Meteoric waters are derived from the rainfall, whereas magmatic waters are yielded by the molten igneous rocks when they reach resting places of diminished pressure and of crystallization and consolidation.

The rainfall has been recognized as the source of underground water from time immemorial. Wells, springs, artesian supplies, and the like were all naturally referred to it. As an obvious, world-wide, and constantly recurring source it had strong claims to confidence. Hence it is not surprising that in the discussions of ten years ago and earlier, the meteoric waters were practically the only ones considered. In 1883, Joseph Le Conte, whose memory geologists on the Atlantic coast cherish no less than do those on the Pacific, wrote an interesting and important paper on the 'Genesis of Metalliferous Veins',[1] in which the subterranean circulations are attributed to this source. In 1893 Franz Posepny contributed to the Transactions of the American Institute of Mining Engineers a more extended paper on 'The Genesis of Ore Deposits,'[2] in which any other source was hardly considered worthy of attention. L. De Launay, the distinguished professor in the higher School of Mines in Paris, in addition to many papers on ore deposits, in 1899 published a fairly large work entitled *Le Recherche, Captage et Aménagement des Sources Thermo-minérales* (Investigation, Confinement, and Utilization of Hot Springs), and the pages show little if any evidence that sources other than the meteoric were in the author's mind. Finally, in 1900, C. R. Van Hise, to whose tireless observation and broad philosophic grasp we, in America, owe so great a debt, most definitely summed up the matter of the underground waters in the paper on 'Some Principles Controlling the Deposition of Ores', before the American Institute of Mining Engineers. In this essay all waters, other than meteoric, are eliminated as of negligible importance and the ground-water of this origin is described as penetrating the earth to the limit of possible cavities. This paper marks the 'high water', perhaps one might say the 'deep water', limit of the meteoric ground-water, and since its publication, the tendency has been strong to see in the magmatic an agent of at least not inferior importance.

As regards the formation of orebodies by solutions from magmatic sources, the first of the important papers appears to be that of Elie de Beaumont, the distinguished French geologist, who shortly before 1850 published in the Bulletin of the Geological Society of France (2nd Series, Vol. IV, p. 1249), a paper in which he connected them with expiring volcanic phenomena. The views, although recently reviewed and elaborated, seem not to have attracted much support in the meantime. The use and development of the microscopic study of rocks about 1870 revealed the minute relationships of the constituent minerals of eruptive rocks and led to much reasoning regarding their order of formation, their collection together in large masses, and the consequent production of orebodies of magnetite, usually titaniferous. This is

[1] American Journal of Science, July, 1883, p. 1.
[2] Trans. Amer. Inst. Min. Eng. Vol. XXIII, p. 213.

especially true of the Swedish geologists of fifteen or twenty years ago and is shown in the writings of M. E. Wadsworth in this country, who was in this important branch of the subject distinctly a pioneer. These well-crystallized basic phases of eruptive rocks first gained general acceptance, but the production of orebodies by so-called 'solfataric' or 'fumarolic' processes were nevertheless not entirely overlooked. Baron von Richthofen appealed to them, when writing of the Comstock lode in 1865; and in a minor way, for easily volatilized ores, such as cinnabar and stibnite, they were doubtless in the minds of others, but they did not play a large part in the thinking of most students of the subject before the early nineties.

At this time the almost constant association of erruptive rocks with our Western ore deposits was more and more realized, because descriptions were becoming available and literature was accumulating. American geologists were facing actual facts and outgrowing earlier and often untenable views and prejudices.[3] Nevertheless, the general view was doubtless that the highly heated intrusive masses served especially to promote activity of circulation in the meteoric ground-waters and few credited them with contributing the waters themselves. The valuable German publication, the *Zeitschrift für praktische Geologie*, began in 1893, and in its second volume, 1894, we find J. H. L. Vogt developing the views on the emission of vapors, gases, and fluids which he described as 'pneumatolitic' and 'pneumatohydatogenic'. These were used in the interpretation of apatite deposits and tin ores, and aroused great interest. In 1895, J. E. Spurr's report on Mercur, Utah, appeared in Part II of the 16th Annual Report of the United States Geological Survey, and on page 449 we find the hot waters that produced the ore, referred especially to a source in an eruptive mass, believed to exist below. Meantime work was active along the gold belt of California and in successive papers we find the characters of auriferous veins and their wall-rocks more and more accurately established. In 1895, Waldemar Lindgren had come to favor a source in the deep-seated grano-diorite and carbonated thermal waters as the vehicle of introduction (Bulletin Geological Society America, VI, p. 240, 1895). It is not stated whether the thermal waters were regarded as coming from meteoric sources that had deeply circulated or as magmatic emisions, but the general disposition at the time was to look upon the former as the only kind of which we were assured and to think the latter of essentially speculative character. Even in the case of volcanoes, most people considered the steam as due to sea-water or rain-water, first absorbed and then emitted.

In the last five years of the closing decade of the past century, there are many indications of a growing belief that the very waters must themselves have come from the eruptives, and no attempt will here be made to trace them in detail. It is my desire to focus attention upon the significant and telling arguments rather than upon the somewhat vague speculation. There are such definite arguments and they are not always distinguished as clearly as they might be from speculative imaginings.

1. Volcanoes and all other eruptive outbreaks visible to us display vast quantities of steam, emitted in such a way as to leave no doubt of its derivation from the molten magma. The magmas certainly contain it and the more acidic ones owe their fluidity in no small degree to it. We find in the quickly chilled rocks or glasses, and especially in the pitchstones that it has been locked up in combination before it could escape. In the rocks formed of anhydrous silicates it has been evicted by the very processes of crystallization and the elimination of gases and vapors, to be subsequently condensed to liquids as a result inevitably attendant upon the solidification of almost all bodies of molten rock.

We may next raise the question whether it is conceivable that the molten rock, while deep within the earth, has been fed by sea-water or descending rain-water, and has absorbed its supplies in this way. Apparently it is impossible because cavities are believed to cease long before the deep seated reservoirs are reached, and because it is beyond belief that water could migrate up to and into a molten mass, rather than be driven outward by heat long before it came within touch of its goal. The water in the still molten eruptive rocks would appear to be an original and component part of the magma, as much as the silica and the bases. The only other possible and partial source would seem to be one suggested by R. A. Daly, and that is, the water combined in hydrated silicates, which constitute sediments and are absorbed by advancing eruptives.

2. An increasing number of deep shafts and boreholes are being sunk in regions that are obviously not areas of expiring but of still animate vulcanism. The latter condition prevails on the Comstock lode. In districts of the former class, except for an occasional slight dampness, whose origin is not necessarily meteoric, these excavations have shown that the ground-waters, chiefly referable to the rainfall, cease at a comparatively slight depth. In first bringing out this point in 1901, I roughly placed the extreme depth as 2000 ft. (Trans. Amer. Inst. Min. Eng. XXXI, p. 187, 1901). The contention has been supported by others since, notably T. A. Rickard[4] and J. W. Finch,[5] and recently in a very interesting way by M. W. Fuller, who, however, while citing with ease and consideration earlier writers who have been apparently wrong on this question, omits all mention of those who have apparently been right.

Mr. Fuller has had wide experience in the hydrographic branch of the United States Geological Survey and has estimated anew on the basis of additional data the actual ground-water in the rocks. It has been customary to express this as a sheet of water over the surface of the globe and of so many feet in depth. Delesse in 1861 gave it 7500 ft.; Slich-

[3] As an example, in the first edition of the 'Ore Deposits in the United States,' 1893, in the concluding remarks, great importance is attached to eruptive rocks. The significance of the statement lies in the fact that the author of the book had been trained under a greatly respected teacher, John S. Newberry, who often and emphatically argued that eruptives were characteristically barren and uninfluential.

[4] 'Ore Deposits, a Discussion,' p. 59, 1905.

[5] 'The Circulation of Underground Aqueous Solutions and the Deposition of Lode Ores.' Proc. Colo. Sci. Soc. Vol. VII, p. 193.

ter in 1902, 3000 to 3500 ft.; Van Hise in 1904, 226 ft.; Chamberlain and Salisbury, 1904, 800 to 1600 ft.; Fuller 1906, 96 ft.[6] Mr. Fuller's estimate distributed on the lower assumption of 5% cracks and other voids in rocks would give a limiting depth of about 2000 ft., and on the higher customary assumption of 10%, would give 1000 ft., either of which is a very interesting corroboration of the early suggestions from actual experience. Veins however in many cases go far lower than these moderate depths.

3. In 1902 the greatly respected Edouard Suess of Vienna delivered a striking address[7] to a convention of medical men gathered at the health resort of Karlsbad, Bohemia, a locality of hot springs, not less famous in America than in Europe, because, also, disordered livers are not limited to either side of the Atlantic. Professor Suess established the following points. The country rock at Karlsbad is granite, a potash-soda rock, while the springs are emphatically lime-bearing and show no connection with the formation from which they emerge. Apparently, they must come from some deep-seated source. Basalts appear to be the most probable mother-rock. For as long a period as chemical analyses have been available, the waters have shown no essential change in composition. They do not vary with the seasons, nor have they any apparent connection with the rainfall. Deep-seated magmatic sources are therefore favored.

A somewhat earlier paper by W. H. Weed[8] describes the Boulder hot springs, in Montana, but he attributes the water to meteoric sources set in active and heated circulation by an intrusive mass. No complete or perhaps very reliable analysis of the water is given, but a commercial one made for the proprietor of the neighboring hotel, contains soda, lime, and magnesia salts with no mention of potash. The country rock is granite with much orthoclase and it would be strange if the water should not show potash unless derived from some fairly deep-seated rock, low or lacking in this alkali. Professor Suess's line of attack might well be followed up in the case of hot springs elsewhere. The evidence of a capacity of a catchment basin and of the possible deep-seated intrusives is somewhat elusive and we cannot altogether avoid a step into the unknown, but the coincidences or the lack of them would be highly suggestive.

There have been other significant observations upon carbonated springs, notably a review of those in Europe by R. Delkeskamp,[9] with the conclusion that the carbonic acid is derived from eruptive rocks. Even at Saratoga, New York, a recent State investigation in connection with the artificial tapping of the waters so as to utilize the gas, has led to the conclusion that some deep-seated and not fully dead eruptive is the most likely source of at least the carbonic acid.

4. The contact zones formed where intrusive rocks act upon limestones seem to demand emissions both of solvents and of dissolved materials, especially iron and silica, in order to explain their actual chemical composition. The points for and against this explanation have been recently set forth in the columns of the MINING AND SCIENTIFIC PRESS[10] and in other places. In the recent monographs of the United States Geological Survey on the Arizona copper districts (except Globe), they are extensively described, but the paper of Lindgren on Morenci has the closest bearing on this subject.[11]

If the general circulation of the meteoric waters is limited to the depths earlier set forth, then it is difficult, even granting that they circulate freely, to establish those contrasts between places of solution and places of precipitation which would be required for the production of veins or other orebodies. The differences of temperature between surface and extreme depth is slight, something like 25°F, perhaps, but the pressure does mount up at approximately one pound per inch, static, for each two feet of water-column. In general, when reasoning about eruptive rocks and their phenomena of crystallization, resorption, and so forth, we usually think of heat and pressure as antagonistic, the former promoting solution and retarding crystallization. While this antagonistic relation may not so fully and may not at all apply to the aqueous solutions within 2000 ft. of the surface, yet it is significant that once we pass the zone of weathering, according to Van Hise, we enter more and more the zone of cementation, essentially one of precipitation. Our orebodies in the latter seem, with a preponderance of probability, if nourished by descending meteoric waters, to have derived their supplies from the limited area of weathered rocks immediately overhead. In speaking of this subject, one cannot help having in mind the lead and zinc deposits of the Mississippi Valley and all that has been written upon them. Even here we may query whether zinc as a matter of observation in its downward journey does not chiefly precipitate as the 'dry-bone' ores at or near the water-level, being thus halted in its course; and whether, even granting its limited subterranean journey, it will be thrown down on emerging unless there should be an intermingling of some positive precipitant such as bitumen or sulphuretted hydrogen, which must be considered a factor no less essential than the area of brecciation itself. Contrasted conditions of some sort are prime necessaries and it would seem as if they had been sometimes rather lightly passed over.

While in the foregoing paragraphs the full depth of 2000 ft. for the general ground-water has been used, yet some have thought with reason that only a part of this is really in motion. Posepny speaks of the deeper portions which are relatively still and which move with great slowness. Finch considers in the 1000 or 1500 ft., which he assigns to the meteoric ground-waters, that the largest and lowest part is practically motionless, unless disturbed by a great fault or an igneous intrusion. Then in the former case for a brief period the water descends, circulates rapidly, and soon heals the wounds with a vein; in the latter case it could only operate above or in the neighborhood of the intrusive. Of course circulation

along or near a fault does not affect, for the acquisition by leaching, a very wide area of subsequently precipitated vein-matter, since if the deeper-seated rocks are tight enough to prevent the ordinary ground-waters reaching them, they would not be widely opened to their passage even by a very great fault.

These considerations are somewhat difficult of sharp mathematical statement and their general bearing and influence are the chief things to weigh. But if we admit the force of the claim that contrasted conditions are essential for solution and precipitation; and if, for cases of orebodies in regions where eruptive rocks as factors cannot be or need not be eliminated, we seek the agent that most efficiently affords them both, then magmatic waters must make a strong appeal.

In preparing the paragraphs above, it has not been the intention or expectation to present anything essentially new, but rather to bring together matter which, for many readers, may be too scattered to be grasped at its full import or even to be known. There has been, also, no desire to over-emphasize the magmatic waters, although their discussion occupies more space, but they are not such well known or easily understood phenomena as the meteoric, and the points regarding them are not so generally a part of every man's fund of information. We seem more and more and somewhat irresistibly tending to believe that at least our Western veins have been deposited in a geologically brief space of time, by waters whose active circulation followed hard upon some igneous intrusion. With much reason we may conclude, following the significant and recently made suggestion of George J. Bancroft,[12] that the waters had access to some new up-welling from the deeper portions of the globe exceptionally rich in the metals. We may think of internal reservoirs of meteoric waters at comparatively small depth invaded and set in motion by the eruptive rock which is leached by them in its cooler stages, or we may imagine magmatic reservoirs emptied by eviction from the molten mass as it solidifies and carrying out the metals in the gangue in solution.

To the ordinary, cold, descending rain-waters we find it difficult to ascribe much effective dissolving action, except in the zone long known to miners as the zone of oxidation, and often now denominated by Van Hise's term as the zone of weathering.

Municipal ownership of coal mines has been discussed for some months by the city council of Vienna, Austria, and it is reported that the city is now trying to secure control of mines in Moravia. The reasons given for the purchase are the high price of coal, and the difficulty of securing a steady supply for the municipal gas and electric plants.

Copper manufacturers are at present working at about half plant-capacity in this country. A slight increase in the domestic demand has taken place, and considerable copper has been purchased abroad for speculative purposes.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

LOCATION OF CLAIM—FAILURE TO MARK BOUNDARIES AND PERFORM WORK.

When a mining claim is properly located by posting the required notice and marking the boundaries within the statutory period, the right to the claim relates back to the time of the posting of the notice and segregates the land from the public domain, and a subsequent location cannot be made until there has been a failure to perform the statutory work within ninety days from the posting of the notice; but where notices were posted and the claims were not staked within ninety days thereafter, the location was not complete, and the claim was not segregated from the public domain, though the posting of notice carried with it the right to define the boundaries within the ninety days.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

LOCATION OF CLAIM—RIGHT OF POSSESSION.

The owner of a valid lode location has the exclusive right of possession and enjoyment of all the surface included within the lines of the location, and this right of possession forbids any trespass. Without the owner's consent or acquiescence, no one can rightfully enter upon the premises, or disturb its surface by sinking shafts or otherwise. It was the intention of Congress to secure the fullest working of the mines and the complete development of the mineral lands, and for this purpose the owner should have the undisturbed possession of not less than a specified amount of surface; and the exclusive right of such possession is as much the property of the locator as the vein or lode by him discovered and located.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

DEATH OF MINER—CONTRIBUTORY NEGLIGENCE.

A foreman in a mine, killed by rock falling from the roof of a tunnel, which the mining company negligently failed to protect, was guilty of such contributory negligence as to bar a recovery, where it appeared that he was an experienced miner and knew that the roof was dangerous, and had not been assured that the place was safe or would be made so, although he was not charged with the duty of inspection, had no authority to supply material necessary to make the place safe, was not bound to use even ordinary care to discover the dangerous condition of the roof, and his superior directed him to work where he did.

Tanner *v.* Wickliffe Coal Co., (Ky.) 108 Southwest. 351, March, '08.

COAL-LAND ENTRY—VIOLATION OF DEPARTMENT REGULATIONS.

The violation of regulations for entering coal-lands cannot be made the subject of a criminal prosecution in the absence of a statute distinctly declaring such violation to be a criminal offense.

United States *v.* Keitel, 157 Fed. 396, Dec., '07.

DEATH OF MINER—PROOF OF PREVIOUS ACCIDENTS.

In an action for damages for the death of a miner killed by falling rock in the man-way of a mine, it was held proper to prove previous accidents occurring shortly before the one in question, for the purpose of showing that the owner of the mine knew that the existing conditions in such man-way were dangerous.

Hotchkiss Mt. & Reduction Co. *v.* Bruner, (Colo.) 94 Pac. 33, March, '08.

CONSTRUCTION OF LEASE.

The provisions of a coal lease as to the payment of royalties were susceptible of two constructions. After receiving the payment of royalties for several years, the lessor could not claim royalties on a different theory.

WATER SUPPLY FOR KALGOORLIE.

Written for the MINING AND SCIENTIFIC PRESS
By M. W. VON BERNEWITZ.

For the purpose of rainfall comparison the State of Western Australia may be divided into four sections, namely, the tropical northwest, with an average rainfall of 24 in.; the middle and southwest coastal districts, with about 33 in.; the eastern and northern goldfields, with 9 in.; and the desert, which comprises about half the area of the State (975,920 square miles), the rainfall over which is unknown.

The East Coolgardie goldfield, of which Kalgoorlie is the great centre, is in the third section, and the following notes refer to its present water supply. During the summers of 1893-94, shortly after this field came into notice, there was a water famine due to the scanty rainfall, and the great rush of those whom the wealth of the country attracted. Water, condensed from steam and still warm, was sold at 60c. per gallon for drinking purposes, and, quoting the words of the Minister for Works in 1902, "I am told—it is hearsay, of course—that hotel-keepers were wont to more jealously guard the manner in which the customer helped himself to water, than to the whiskey bottle; and in regard to water for bathing purposes, out of respect to the feelings of many prominent citizens, I will draw a veil."

There always was a fair amount of salt water available for mining purposes, but for boilers and domestic use it had to be condensed, and for milling it was not satisfactory at all. As mining operations extended and the population grew on the Coolgardie and Kalgoorlie field (population of the latter now being 29,000), the water question became serious.

Many schemes were proposed, some for pumping fresh water from rivers near Perth, salt water from the sea on the south coast (200 miles), condensing the local salt water on a large scale, and building big storage dams on the fields. They all fell through. Definite steps were taken in 1895, when C. Y. O'Connor, then Government Engineer-in-Chief, reported to Sir John Forrest, then Premier of the State, on a scheme for damming up one of the valleys in the Darling ranges, about 30 miles from Perth. Seventeen valleys were examined, and that of the Helena river, at Mundaring, was decided upon as the most suitable for a reservoir. This is now known as the Mundaring reservoir. Toward the end of 1896 a bill passed Parliament, after much opposition, for raising a loan of $12,500,000 for the construction of the waterworks. Up to date the scheme has cost $15,700,000. The reservoir has a catchment area of 570 square miles, with an average rainfall of 33 in. per annum. It holds, when full, 4,680,000,000 gal., and the water is dammed back some 8 miles. The weir is 725 ft. long at the top, 100 ft. high, 85 ft. thick at the bottom, with uniformly decreasing thickness to the top, where it is 8 ft. The upper side or face of the wall is vertical, the whole being of concrete. The illustration shows the arrangement at the top for the flood-waters, the valve-tower, and the off-take and scouring-pipes at the bottom.

The Mundaring Reservoir, Western Australia.

In putting in the foundations a fissure, due to an intrusion of diorite through the granite of the river bed, caused much extra expense to make a good job. The reservoir has filled every season since 1903; and in 1907 it is estimated that 15,000,000,000 gal. ran to waste. Steps are now being taken to connect up with the mains of Perth and its suburbs, having a population of 50,000. The total cost of the reservoir, including a 4-mile railroad with a 4% grade, was $1,240,000.

The pipes are 30-in. diam by 28 ft. long, consisting of steel $\frac{1}{4}$ and $\frac{5}{16}$ in. thick. There are 66,600 joints of the pipe, making in all 353 miles. The pipe was made locally on the Mephan-Ferguson patent locking-bar system. The joint rings are of the sleeve pattern, run up with lead, and caulked with a patent caulking machine. Including valves, specials, trenching, etc., the pipes cost $8,900,000. The pumps are horizontal, high-duty, duplex, direct-acting, 6-cylinder, triple-expansion, Worthington engines, with pump plungers externally and centrally packed, and the engines furnished with surface condensers and air-pumps. There are 12 pumping stations, with a

total of 20 engines and 20 Babcock & Wilcox boilers, the latter fitted with superheaters, feed-water heaters, and economizers. Two men only are required per shift at each station. The steam cylinders are 16, 25, and 46 in., with a 36-in. stroke; and 12 of the pumps have double-acting plungers of 15 in. diam., the remaining eight have plungers 21 in. diam. The steam valves are of the Corliss type. Each duplex engine takes 300 hp., with steam at 175-lb. pressure. The bottom of the reservoir is 340 ft., and the distributing reservoir at Kalgoorlie is 1375 ft. above sea-level. The capacity of the pumps is 5,600,000 gal. per day. Actual pumping costs are 20c. per 1000 gal. The pumps, boilers, buildings, sidings, etc., cost $2,149,000.

ANALYSIS OF THE WATER.

Silica	0.26	gr.	per	gallon
Iron and alumina	0.34	"	"	"
Carbonate of lime	1.62	"	"	"
Sulphate of lime	0.70	"	"	"
Carbonate of magnesium	0.99	"	"	"
Chloride of magnesium	2.72	"	"	"

	24.24	"	"	"
Solids in suspension	17.00	"	"	"
Total solids	41.24	"	"	"

During the last fiscal year of the work the total water consumption amounted to 688,548,000 gal., which was sold at prices from 24c. to $2.40 per 1000 gal. The Kalgoorlie group of mines now takes 1,000,000 gal. daily. Leakage and evaporation from the reservoir, service reservoirs, and main pipes is estimated at 140,000 gal. daily.

The cost of the installation was $15,700,000, and the operating expenses are $325,000 per year, while the revenue in 1906-07 amounted to $835,000. This, of course, is insufficient to meet interest account and provide a sinking fund, so that the estimated deficit is $420,000 for the year, but the benefit to the mines and the community has been almost incalculable.

Two Years' Fire in a Mine.—A report from Broken Hill states that a little inconvenience is being experienced on the Proprietary mine in connection with the Block 12 fire, which has been burning nearly two years. The fire has extended right up to the water curtain, on the north side, and the smoke and gas are passing through the water into the workings. Several men have lately been affected by the gas. There is no reason to suppose that the fire will extend beyond the water curtain, though the extension of the fire is causing anxiety. When this fire broke out it was the third occasion on which the mine had been on fire. On Sunday night, July 25, 1895, an outbreak was discovered. The second outbreak occurred on Sunday morning, September 12, 1897. It is not known how long this burned, for it was in a portion of the mine which was worked out, and the locality had been completely blocked up. The fire now burning began on a Saturday night in February, 1906. It was attributed by the general manager to a blast which had been fired and carelessly left, because it was 'crib' time. When the men returned the gallery was full of smoke, so that it was impossible to turn on the water, of which there was an abundant supply close at hand, and an effort was made to drown the fire from the 300-ft. level, and to smother it by blocking out the draft. It has steadily crept along as far as the water curtain on the north side.—*Queensland Mining Journal.*

Artesian Basins.—The presence of artesian conditions in an area is frequently inferred by geologists from a study of rock structure. In what is properly termed an artesian basin the layers of rock are bent downward, so as to resemble a pile of shallow plate-shaped dishes placed one within another. One or more of the beds of rock is porous and allows water supplied by rain on its upturned edges to percolate into it. Above and below the water-charged layers are close-textured rocks, like clay, that prevent the escape of the water in the bed between them. A number of such structural basins are found in the region studied by I. C. Russell of the U. S. Geological Survey. Confirmation of the supposition that water under pressure exists beneath the surface in any area is found at many places in the occurrence of warm springs—those with temperatures ranging from 60 to 100°F. As the water in artesian basins has descended from the surface, and as the temperature of the earth increases with depth, the deeper the water has penetrated into the rocks the higher will be its temperature. The increase in the temperature of the earth below a depth of about 50 ft. in temperate regions is in general about 1°F for each 60 ft., but there is considerable evidence favoring the conclusion that in southern Idaho and adjacent parts of Oregon the rate of increase is approximately 1°F for each 45 ft. in depth. At the depth of 50 ft. the temperature corresponds to the mean annual temperature of the locality chosen, which in this region is approximately 50°F, so that if a spring in this region has a temperature of 65°F. or 15° above the temperature of the stratum of no seasonal variation, it would be safe to conclude that the water rises from a depth of at least 675 ft. below that stratum, or 725 ft. below the surface. Such a spring would therefore serve as an indication of the depth to which a well should be bored to penetrate the water-charged rock layer. Mr. Russell calls attention to the fact that while warm springs may indicate the presence of a water-charged layer that would supply flowing wells, a hot spring, or one having a temperature of more than 100°, is not so favorable an indication. Hot springs ordinarily rise from depths so great that even if they come from a well defined water-charged layer it would be unavailable as a source of supply for most purposes for which artesian water is used, as the expense of drilling to reach it would be unjustifiable.

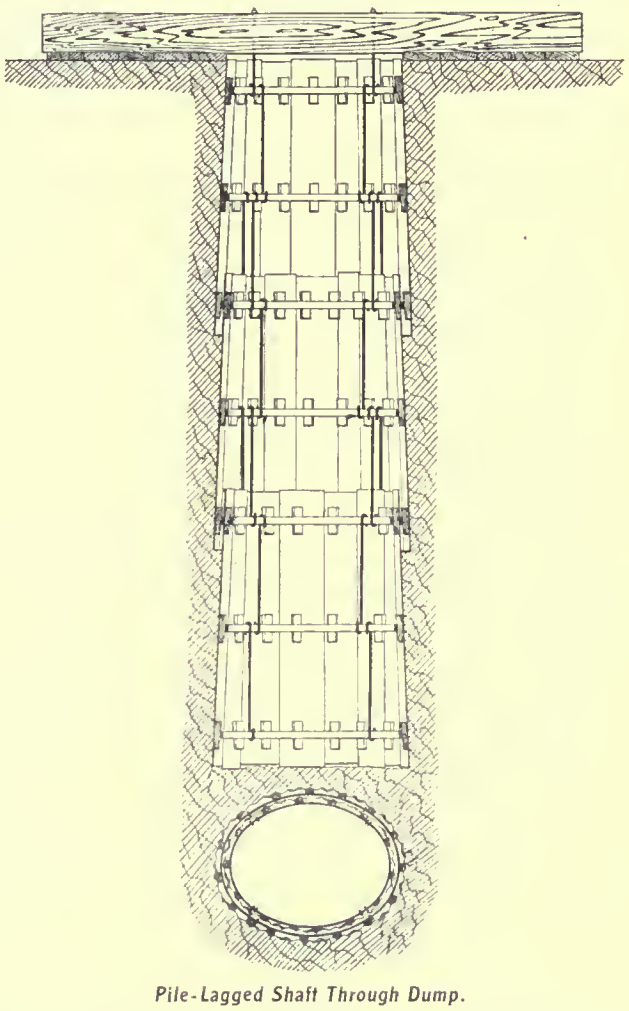
The Director of the United States Mint estimates that the world's consumption of the precious metals in the arts alone, that is, for manufacture of jewelry of all kinds, gold filling for teeth, gold leaf for gilding, etc., was 5,882,000 oz. of fine gold, valued at $121,500,000, and 85,196,000 oz. silver, valued at $57,500,000. These figures represent absorption of these metals into the arts for the single year 1907.

SAMPLING OF MINE DUMPS.

By Henry S. Munroe.

*The sampling of waste dumps presents a difficult problem. Portions of the dump result from periods of development work in barren rock, while other portions, representing the growth during periods of wasteful or careless management, may be very rich. If the dumps are formed in the ordinary way, by dumping cars at the top of the bank, the stratification and therefore the zones of rich and poor material will be in inclined layers. Moreover, as the cars are dumped at the top, the larger pieces tend to roll to the bottom of the slope, while the fine stuff lodges and remains near the top. The upper portion of the dump contains most of the fine material, and is therefore likely to be rich; and the bottom, consisting of lumps and coarse material, is in general poorer than the average. The usual method of sampling a dump is to take numerous small samples from the sides and top, which are either assayed separately or combined. If this method is adopted, the points to be sampled should be determined by measurement on contour lines at regular intervals, and at the corner of 25-ft. squares on the top. In any case, due weight should be given to the tonnage represented by each sample. In dump sampling, a small crushing plant is essential, owing to the large size of samples required. In most cases, a careful sampling is necessary, and such expense is inevitable.

The following is a method of sampling adopted in Bolivia in sampling large dumps in a district where timber was expensive and corrugated iron could be obtained at a reasonable cost. In order to avoid the sources of error incident to sampling in the ordinary way, and to reach the deeply buried portion of the dumps, which were believed to be rich, it was decided to attempt the sinking of vertical shafts through the dumps to obtain the desired samples. The advantages of this method of dump-sampling are obvious. Each shaft traverses numerous inclined layers, and gives information as to the contour of the ground which is required in making the estimate of tonnage. Small elliptic shafts were sunk, but owing to the loose dry character of the ore, it was necessary to drive some form of spiling every few inches. Plank and timber being expensive, it was decided to use light iron rings backed by sheets of corrugated iron, a material which is commonly used in South America for building purposes. This was cut into pieces of suitable size, and made excellent poling boards, light and stiff and occupying little space in the shaft. By reason of its smooth surface, the iron sheets drive easily, with but little friction, requiring light blows only of a 3-lb. hammer. After experimenting with sheets of different sizes it was found that the best results were obtained with pieces about five feet long and a foot or less in width. To support this corrugated iron lining, elliptical rings of ⅜ by 1½-in. bar iron were used, the ends being welded together. The rings were made of elliptical rather than circular form, to permit the large bottom rings of each set to be passed through the smaller upper rings. Also the elliptical form, for equal areas, gave the workmen more room for pick work and shoveling. These rings were supported by hooks of ⅜-in. rod. After experimenting with rings of different sizes, the dimensions indicated below were adopted, the middle ring being 32 by 38 in. and the upper and lower ring respectively 2 in. smaller and larger each way. A shaft of these dimensions can be sunk rapidly and gives a sample of manageable size. With small men it proved practicable to use rings of less dimension than this. In one case a shaft was sunk successfully to a depth of 22 ft. with rings averaging 22 by 28 in. In all, nine shafts were sunk in eight weeks time, the deepest being about 60 ft. This system of shaft-lining, though composed



Pile-Lagged Shaft Through Dump.

of light material, possesses considerable strength and stiffness. The over-lapping of the corrugated sheets and the double rings, tightly wedged together where the sections join, add much to the strength of the lining. The hooks are elements of weakness, as these will straighten out at about one-fifth of the ultimate breaking strength of the rods. The strength of these hooks may be increased by always inserting the point of the upper hook in the space between the ring and the corrugated iron sheets, and by fastening the point of the lower hook to the rod with a slip ring. The work of shaft-sinking will be facilitated by having on hand extra hooks, shorter and longer than the standard length. It will be well also to have a number of hooks with turn-buckles, to replace hooks that may be broken elsewhere than at the bottom of the shaft.

RECENT CYANIDE MILL IN MEXICO.

The cyanide plant of the Guanajuato Reduction & Mines Co., started with 80 stamps, milling 250 tons per day, being the first unit of a proposed 1000-ton mill, the second unit of which was put in operation in August 1907. The ore is first crushed through a No. 5 Gates crusher, passes to a sorting-belt, and thence to a trommel with 1⅛-in. apertures. The oversize is crushed in a No. 4 D Gates crusher. The mill construction is of steel throughout, the batteries set back to back, 80 on each side. These stamps are all of 1050-lb. weight, making one hundred 8-in. drops per minute. The mortars are set directly upon concrete foundations without anvil block. The stamps are driven in batteries of 40 to a shaft, one 100-hp. motor driving each 40 stamps. The ore is crushed in 0.04% KCy solution through 26-mesh 28-gauge steel-wire screens, and is classified by spitzkasten into two bottom products and an overflow. The coarse product from the first spitzkasten is concentrated over No. 4 Wilfley tables, practically the entire tailing from which is re-ground in tube-mills. The fine spitzkasten-product is concentrated on No. 4 Wilfleys, the tailing going directly to the cyanide plant. The overflows from the spitzkasten are all elevated to large thickening cones, the bottom product being concentrated on Risdon-Johnston tables, as is also the tube-mill product. There are 24 Wilfley tables, 18 Risdon-Johnston concentrators, and one Overstrom in the mill. Two Abbé tube-mills, 4 ft. 6 in. by 20 ft., do the re-grinding, using silex lining and No. 4 Danish pebbles. The average life of the linings has been eight months.

The mechanical efficiency of the mill is well demonstrated by the fact that during the first year of operation the total loss of possible stamp-hours amounted to only 0.87%, this including all renewals of shoes and dies, screens, belts, etc. The total tailing passes through a tunnel and sampler to 6 thickening cones 20 ft. diam. with 45° sides, the clear overflow being pumped back to the mill-supply tank 22 ft. diam. by 20 ft. high. The thickened product, carrying about four tons of solution to one of pulp, is then introduced into a cast-iron pipe with bell-and-spigot joint, 8 in. diam., ⅝ in. thick, and 5440 ft. long, which conducts it to the cyanide plant a mile away. This line is laid on a uniform grade of 2¼% for its entire length, except for the 800 ft. at the head of the line, which has a grade of 3½%. No difficulty whatever has been experienced in the conveyance of pulp through this line at the thickness mentioned, and after having conveyed 150,000 tons of ore there are no appreciable signs of wear in the pipe.

At the cyanide plant, classification into sand and slime is effected by four 8-ft. cones without ascending current, and the bottom product is again put through sixteen 4-ft. cones with ascending current, the overflow from all cones going direct to the slime-plant. The bottom product of the 4-ft. cones goes through Butters distributors to one of three receiving tanks 48 in. diam. and 8 ft. high, with filter-bottom. These are filled in rotation, drained and discharged through bottom-discharge gates to a conveyor belt system which passes over the centres of 15 leaching vats each 40 ft. diam. by 8 ft. high. After treatment the sands are sluiced into the river; 15-day treatment is given, involving 30 baths of 0.5% and 6 baths of weak stock-solution. The slime is treated by decantation, the residues being passed through a Butters filter. All decanted solutions pass through the zinc-room before returning to the stamp-mill. The Butters filter contains 75 leaves, and handles 220 tons of dry slime per day.

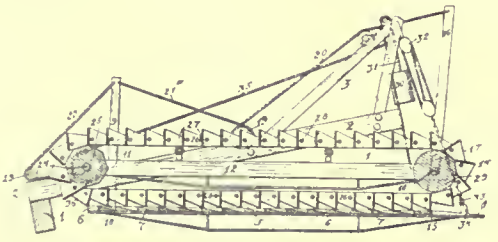
Battery chips may be conveniently assayed by removal of the iron as matte and the concentration of the gold in a lead button. With careful manipulation, the gold in the matte may be reduced to a negligible quantity. The chips usually consist of pieces of iron from the size of a pin head to as much as half an inch in diameter. The scorification assay is useless, owing to the small quantity that can be treated. The solution of the iron by acids is slow and expensive. The best method is to assay 1 A.T. of chips by passing the iron into a matte free from gold, and collecting the gold in a lead button. A charge with 50% of sulphur to the chips taken, yields a perfectly malleable lead button, and a matte carrying practically all the iron originally in the charge. As in the assay of copper ore, care has to be taken that no excess of litharge is left in the slag, as any excess of sulphur would yield an exceedingly large button. An iron nail should be used in all cases, to keep the button malleable and the matte free from lead. The following charge yields excellent results with battery chips: chips, 1 A.T.; soda, 1.5 A.T.; fused borax, 1.5 A.T.; sulphur, 0.5 A.T.; silica, 0.5 A.T.; charcoal, 1 gram; and an iron nail. Silica is added to protect the crucible, and an excess of flux is used. After a quick fusion the charge is given a wash-down with a small quantity of litharge and charcoal. In this assay, the furnace used for fusion must run at a slightly higher temperature than is usual for a gold assay, and the crucible must be allowed to remain in the furnace for 20 min. after quiet fusion. If the heat be insufficient or the charge be poured too soon, the iron will be found in small lumps on the top of the lead button, and not completely absorbed into the matte. Generally the battery chips assay less than 6 oz. per ton, and the amount of gold in the matte is not weighable. In cases where the estimation of silver is required, it is necessary to save the matte and recover the silver by scorification. The sampling of battery screens often presents difficulties, but this may be overcome by giving a weighed quantity of battery screens an oxidizing roast, after which it can be pulverized easily and assayed by the same method as battery chips.—Leslie J. Wilmot.

The tower of the Metropolitan Life building, now in process of construction at Madison Square, in New York City, and which is already the highest building in the world next to the Eiffel Tower, at Paris, is to have 37 ft. added to its height, thus bringing the total number of stories, including two in the basement, up to 50, and the top of the surmounting glass ball 693 ft. above the sidewalk level.

MINING AND METALLURGICAL PATENTS.

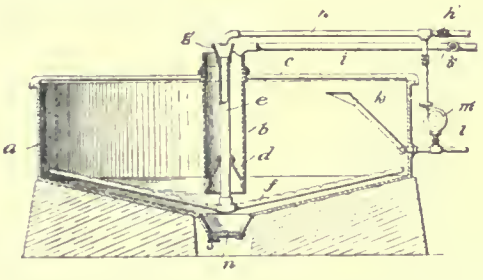
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MINING-DREDGE.—No. 886,728. Thomas P. Rochford, Valdez, Alaska.



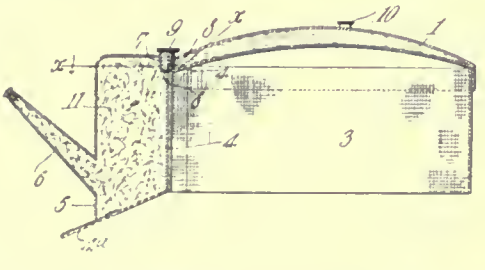
In a mining-dredge, the combination of an inclined sluice-box provided with an open top, gold-collecting riffles upon the bottom of the box, a digging shovel at the front end of the box, means for supporting the box with its front end submerged in a body of water, means for oscillating the box longitudinally to cause its shovel to loosen the gravel, and an endless rotary elevator arranged in the top of the box for elevating the gravel loosened by the shovel.

SLIMES TREATMENT.—No. 886,900. Charles E. D. Usher, Johannesburg, Transvaal.



The hereindescribed process of treating metalliferous slime which consists in maintaining said slime in a state of suspension by the upward passage therethrough of a solvent or wash liquid, at such a rate as not to materially disturb the homogeneity of the slime and collecting the clear liquid above the slime.

MINER'S LAMP.—No. 886,441. Samuel J. Thompson, Bluefield, West Virginia.

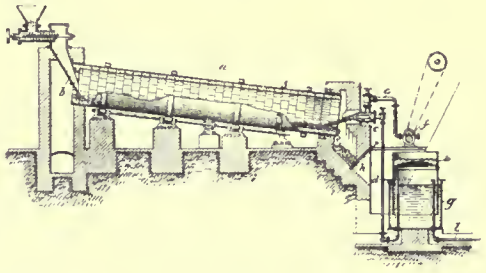


A cap having a front guard-plate, a vizor extending therefrom, a receiver, said vizor and guard-plate constituting the bottom and rear wall respectively of the receiver, a concavo-convex reservoir extending from the upper portion of the guard-plate and opening into the receiver, means for controlling the passage of oil from the reservoir to the receiver, a plate-holder extending from the receiver, and a flexible band secured to the guard-plate and to the edge portions of the reservoir, said reservoir constituting the crown of the cap.

PROCESS FOR EXTRACTING METALS.—No. 886,866. Dennis R. Robertson, Denver, Colorado.

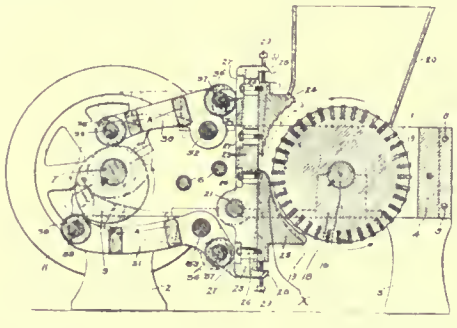
The herein described process of extracting gold, or gold and copper, from ores containing the same, which consists in adding to the partially pulverized crude ore aqua regia, agitating and applying steam to the mass until it is brought to the boiling point, and adding 20% of cold water, filtering, and adding iron to the filtrate, while retaining the mixture at approximately 70 degrees.

PROCESS FOR THE BALLING TOGETHER OF PULVERULENT OR DUSTY ORES.—No. 886,683. Hugo Dicke, Frankfort-on-the-Main, Germany.



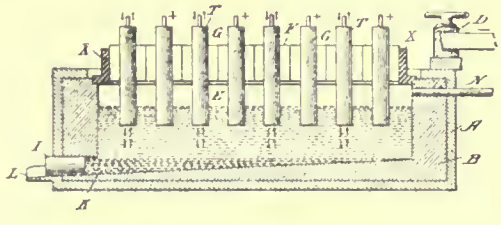
The method of balling together or nodulizing of dusty pulverulent ores or ores of small size of grain, with, if desired, simultaneous oxidation or reduction in the rotary furnace, which consists in subjecting the ores to a heat of at least 1000 degrees, by a pointed flame whose shape may be adjusted and having an oxidizing capacity in the zone of the furnace which is limited by said flame.

ORE-CRUSHER.—No. 887,003. Charles O. Michaelsen, Omaha, Nebraska.



In an ore-crusher, a roller having a plurality of longitudinally extending bars of hard material set in the peripheral surface thereof, a rocking-lever pivoted adjacent said roller, jaw-blocks of hard material secured to said rocking-lever adjacent opposite ends thereof, the faces of said blocks working adjacent and co-operating with the roller to crush materials between the same, means for adjusting the positions of said jaw-blocks longitudinally of the rocking-lever, a cam, cam-levers actuatable thereby, said cam-levers engaging the rocking-lever to actuate the same, and means for simultaneously actuating the cam and the roller.

ART OF REDUCING ALUMINUM AND OTHER METALS.—No. 886,757. Henry S. Blackmore, Mount Vernon, New York.



The process of reducing metal from substances containing the same, which consists in fusing the metal-containing substance by passing a non-metal-yielding current through the fused material between contacts, and liberating the metal from its compound by the action of a metal-yielding current passed therethrough in a path disposed parallel to or with the path of the heating or non-metal-yielding current.

ELECTROLYTIC PROCESS OF PRODUCING METALS.—No. 886,857. Edgar F. Price and William S. Horry, Niagara Falls, New York.

The process of producing alkali or alkaline-earth metals, which consists in electrolyzing a molten salt of the desired metal with an anode essentially comprising a carbide of that metal.

MINE REPORTS.

NORTH STAR MINES, NEVADA COUNTY, CALIFORNIA.

During the year ending December 31, 1907, the North Star mines produced a total value of $937,816, at a cost for current operation of $398,935 and for development of $93,020, or a total outlay for operating and development of $491,955, leaving an available profit of $445,860. Outlays during the year for improvements, $42,195, and property purchase, $344, amounted to $42,539, leaving a balance of $403,320. Interest earned during 1907 amounted to $22,760, increasing the total net earnings from all sources for the year to the sum of $426,081. Out of this were paid dividends amounting to $250,000, 10% on the capital stock, leaving a surplus of $176,081 to be added to the company's available cash resources, amounting, at the end of 1907, to about 30% of the total issued capital.

The above sum was produced wholly from the North Star mine, from 78,366 tons of ore milled, being an average yield of $11.967 per ton, at an average cost of $5.091 for current operation and $1.187 for development, aggregating $6.278 and leaving a realized profit of $5.689 per ton over all costs of operation and development. Outlays during the year for improvements and property-purchase amount to $0.543, leaving a net mining profit, over all outlays, in cash surplus, of $5.146 per ton of ore.

The ore produced was about 6300 tons less than in 1906, by reason of a labor strike, which interrupted productive operations during January and February, 1907. Fortunately the improved quality of the ore more than compensated for the lack in quantity, so that the value of the output for 1907 considerably exceeded that of any previous year. Of the above stated total tonnage, the old or upper workings of the North Star mine, on and above the 2700-ft. level, operated through the incline shaft, produced 21,211 tons, yielding $296,798, or an average of $13.993 per ton, at an operating cost of $129,037, or $6.084 per ton, and a resulting profit of $167,761, or $7.909 per ton. The outlays for development and exploration in the old or upper mine, during 1907, amounted to $35,724, or $1.684 per ton, giving a total cost of $164,762, or $7.768 per ton, and a net mining profit of $132,036, or $6.225 per ton of ore. During 1907 the deep or lower North Star mine, comprising all workings below the 2700-ft. level and operated through the Central vertical shaft, produced 57,155 tons of ore, yielding $641,018, an average of $11.215 per ton, at an operating cost of $269,898, or $4.722 per ton, and a resulting profit of $371,120, or $6.493 per ton. Additional outlays for development and prospecting work in the lower mine, during 1907, amounted to $57,295, or $1.002 per ton, making for operation and development together a cost of $5.724, and leaving a net mining profit of $313,824, or $5.491 per ton of ore.

These actual operations of last year fully realize the favorable indications of previous reports and warrant the reasonable expectation that, under present conditions of operating capacity and the now visible or probable ore supply, the mine may continue to produce similar results during many years to come. The results of development and prospecting work during 1907 have been satisfactory, both in the upper and the deeper levels of the mine. At the close of 1906, as stated in the report for that year, the visible ore resources in the old upper mine were very small and unpromising, but the persistent extension of prospecting drifts fortunately disclosed good ore on various levels, resulting in profitable operations for 1907, as shown in the figures herewith submitted. In the deeper levels, now the main sources of production, the stopes have continued steadily to yield a full supply and a somewhat better quality of ore than in the two preceding years. The developments in the extreme bottom of the mine are especially satisfactory. Drifts have been extended in both directions on the 4400 and 4700-ft. levels with encouraging results. The sinking of the incline shaft, following the vein downward from the 4000-ft. level, at the bottom of the Central vertical shaft, was resumed October 1, at the point where previous sinking had ceased, somewhere below the 4700-ft. level, and at the end of 1907 this work had reached a depth of 5000 ft. from the outcrop, measured on the dip of the vein, or 2000 ft. vertically below the overlying surface. In this work the shaft was sunk in ore for 150 ft. of its course, disclosing a vein from 3 to 6 ft. thick, of rich quartz, which now promises to be the source of much profit.

It may be noted here that the North Star mine, in its career of nearly 50 years has been more or less continuously ore-bearing from the surface to the present bottom, nearly a mile deep on the dip of the vein, and that at the present time the current production of ore is contributed from practically all the different levels opened in the mine at depths varying from about 1500 to 5000 ft. below the outcrop.

The outlays for improvements during 1907, amounting to $42,195, were made mainly for equipment account, partly for the completion of the cyanide plant at the old North Star mill and partly for electric and air-compressing machinery at the power-house. The cyanide plants of both mills are in successful operation, treating all the mill-tailing with satisfactory results. At the Central plant the cyanide process has been successfully adapted to the treatment of the sulphide product of the mills, yielding better economical results than were formerly obtained by chlorination or smelting.

The present condition of the property and its equipment is in all respects satisfactory; while the prospective outlook is reassuring and very encouraging.

LUCKY-TIGER COMBINATION GOLD, SONORA, MEXICO.

The Lucky-Tiger Combination Gold Mining Co., a Kansas City corporation, operating at El Tigre, District of Moctezuma, in the State of Sonora, Mexico, reports for the year 1907 a net profit of $283,662, from 15,255 tons of ore, having a value of $655,875, or $238 per ton. Of the above output, 1768 tons was shipped as mined, yielding $255 per ton, and 13,487 tons went through the mill, producing 980 tons of concentrate, worth $204,185, or $208 per ton. The operating profit was $386,053, and the net profit after adding income from rents and store was $409,022. Expenses at the home office, including interest on a $400,000 bond issue at 6%, was $26,370, to which was added cost of litigation amounting to $98,988, reducing the net gain on the year's operation to the figure first given. The gross value of ore and concentrate produced to date is $1,428,875, and the net return to the company, after paying freight and export duties, was $1,308,427. The total output of the property has been 15,693 oz. gold and 1,851,401 oz. silver. Out of the net operating profits the sum of $115,518 was expended on improvements, and $500 was paid as the purchase price for the Espuela claim, making $116,018 put back into the property, leaving a balance of $167,644 applicable to the payment of dividends or to the retirement of bonds. According to the terms of the mortgage the company is obliged to retire bonds at the rate of $5000 per month beginning with April, 1907, and $7500 per month beginning March 31, 1908, so that, having purchased and retired bonds to the amount of $92,800, the company has not only fulfilled all requirements to date, but has more than anticipated such obligation as far ahead as June 30, 1908. The report mentions a net undivided profit of $548,964, but this represents operating profit as shown on the books, and is evidently not a surplus in hand available for distribution. To that extent the statement, as made, is misleading. The company's policy of absorbing a portion of net earnings into betterment, instead of hastening to declare dividends, indicates a disposition to make money out of mining instead of from stock manipulation.

The Lucky-Tiger property was operated from May, 1906, to December, 1907, by an interventor appointed by the Mexican Court, pending a decision of a spectacular case involving a seizure of the mines and works in 1905 by an armed band under a pretext which the Supreme Court has failed to justify. The closing of this romantic incident, under the attendant circumstances, is as much a vindication of the stability of property rights in Mexico, as of the company's pretensions.

GATES ELEVATORS.

Gates elevators exceeding certain lengths, are made in sections joined together by iron plates and bolts. Erect the elevator as nearly as possible on the same angle as shown in plan for erection of plant, as their efficiency diminishes if they are either too flat or too steep. Be sure that your foundation is solid enough so that there is no liability of its settling and see that it is perfectly level, so that when the lower end of the elevator rests upon it there will be no twist in the frame work. If both sides do not rest solidly on the foundation, either 'scribe' and 'trim' to fit, or wedge up with shingles. Having the frame work set and well braced on the back side, as shown in the plans, the manner of putting on the belt and attaching the buckets is as follows: Put a piece of pipe or wood through the arms of the lower pulley to keep it from turning. Put on the belt-clamps, allowing the lower end of the belt to lap on top of the upper end at least the length of two buckets, and stretch the belt somewhat looser than you would if the belt were going to be used for transmission purposes. Place a bucket on the belt with its upper edge flush with the end of the lap of the lower end of the belt, dividing the space on the belt equally, on each side of the bucket. Whittle the end of a stick small enough to enter the holes for the bucket-bolts and, dipping the end into paint, varnish, or ink; mark the belt through the bucket bolt holes. Place a piece of hard wood under the marked spots and with a belt-punch (two of which are sent with each elevator) punch a hole through each of the spots. Raise the belt and insert a bolt in each of the holes; place the bucket back in position and screw on the bucket with the socket wrench (which is sent with the elevator). Place another bucket close against the first bucket, mark, punch, and fasten same. You will now have the belt securely fastened together and can remove the belt clamps.

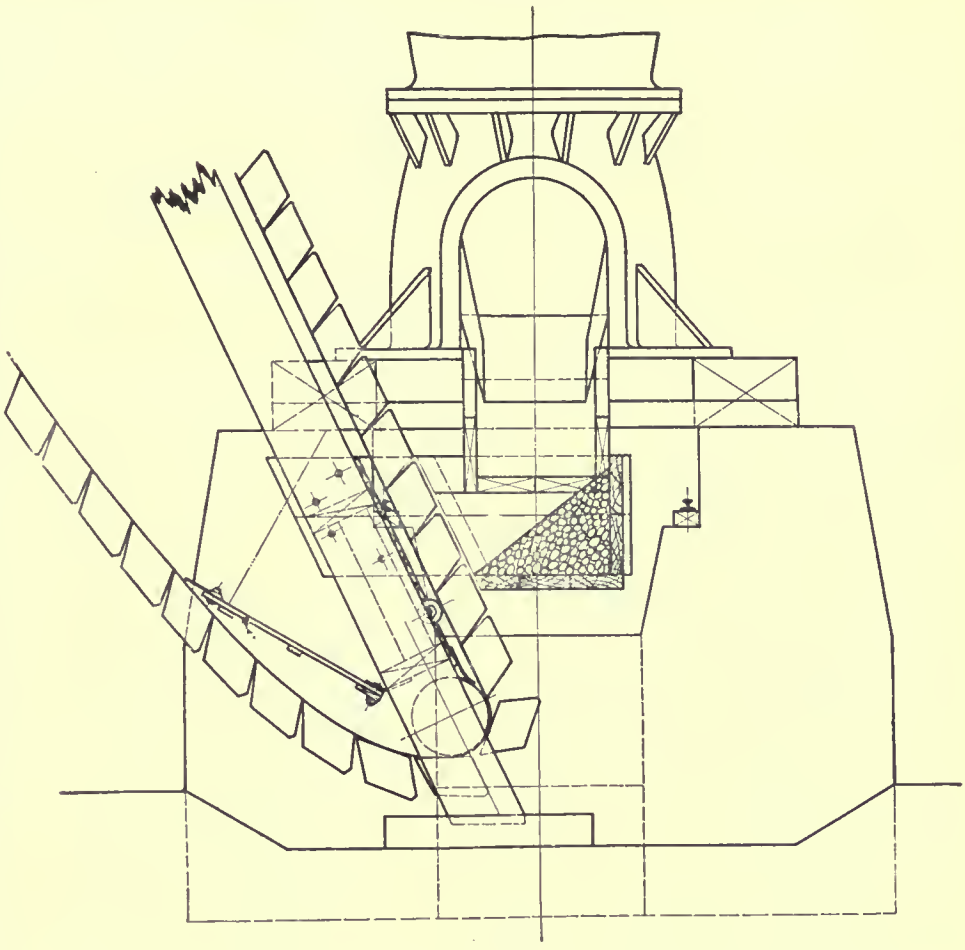


Fig. 1.

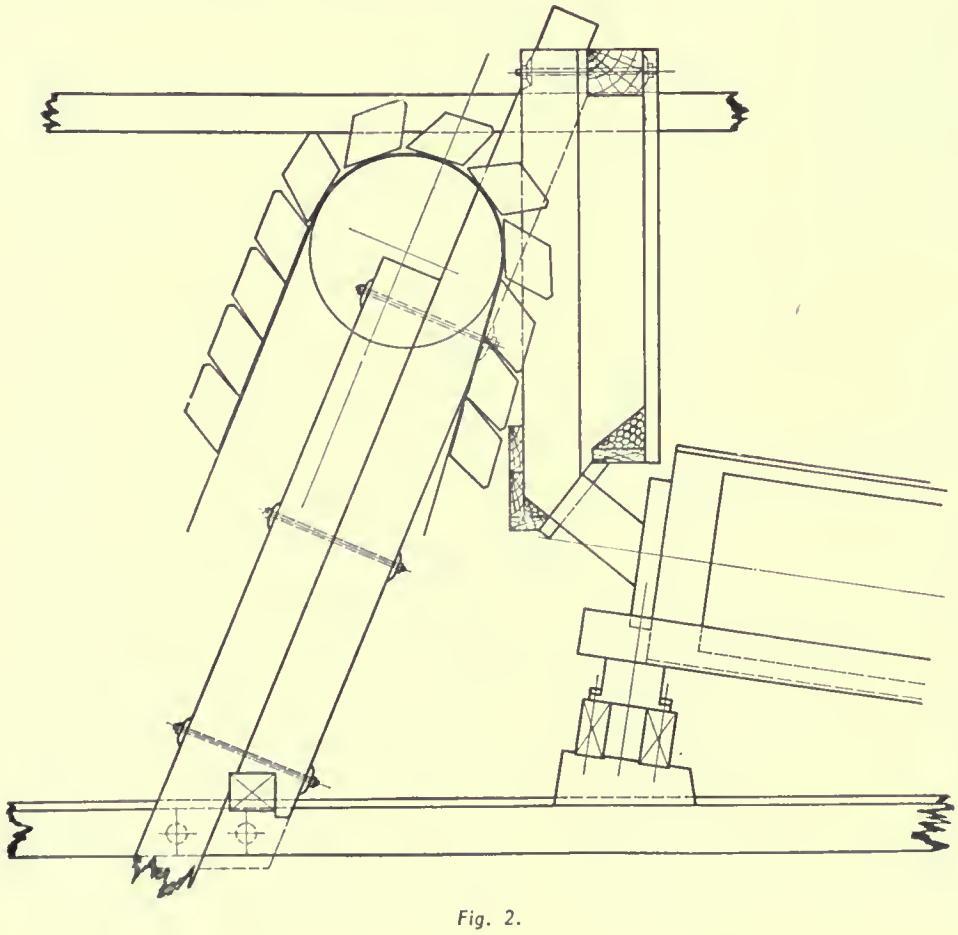

Fig. 2.

Let the two buckets drop down about the length of a bucket, and, putting another bucket close against the upper bucket, mark and fasten on the belt as heretofore directed. Fasten another above the last, and so on until all are on except about twenty buckets; then measure the space left on the belt (also measuring the length of one of the buckets) and divide any surplus over that required for the number of the buckets which will be needed, so that there will be an even amount of space between each

of the remaining buckets, and not the entire surplus space between the last bucket put on and the one above it. Oil the journals and put on the grease cups preparatory to starting. Do not stretch the belt too tight, but let it run with a large amount of slack so that it sags well out at the lower back side. If the belt stretches in use so much that the room in the tightener is exhausted, cut off the belt at the lap between the first and second buckets, and draw up the second bucket to its place; thus making the second bucket take the place of the first bucket, and the third bucket the place of the second, thereby completing the fastening of the belt as in the first instance.

When the elevator is to be stopped, run it at full speed until the buckets are empty. When shut down gradually with the buckets full of material, the stone cannot be properly discharged and falls between the bucket and the belt, punching holes through the latter and destroying it. A proper shield should be arranged over the inner face of boot pulley, as shown in Fig. 1, to prevent stone which may fall from above from getting between the pulley and belt, as this also results in destroying the latter. In spouting into the elevator there should always be two buckets on a straight line below the bottom side of the feed spout; this enables the second and third buckets to catch the material before it gets in behind the bucket that is just coming around the pulley. (See Fig. 1.) On the discharge or upper end of the elevator, it has been found the best practice to have no less than three buckets on a straight line above the spout, as illustrated in Fig. 2. This gives the stone more of an opportunity to drop into the spout of the screen, or any spout provided for the purpose, before being carried past and falling on the floor below.

COMMERCIAL PARAGRAPHS.

THE ATLAS CAR & MFG CO., Cleveland, Ohio, has issued bulletin No. 1065, describing side-dump cars.

THE BARTLETT & SNOW CO., Cleveland, Ohio, has issued catalogue No. 25, describing crushers, pulverizers, and feeders.

THE SWEETLAND FILTER PRESS CO., Los Angeles, recently shipped a Sweetland filter press to the Monica Mines Co., Kirkland, Arizona.

THE J. GEO. LEYNER ENG. WKS. CO., Littleton, Colorado, has issued bulletin No. 514, describing its line of steel-sharpening apparatus.

THE GOLDSCHMIDT THERMIT CO. announces the establishment of a branch office and works at 103 Richmond St., West, Toronto, Canada.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY CO., Denver, Colorado, has issued its regular monthly Announcement and List of Machinery and Supplies for May.

ALLIS-CHALMERS CO. has issued a publication called 'Modern Rock-Crushing Plants,' containing information on the installation of machinery used for crushing.

THE C. H. SHAW PNEUMATIC TOOL CO., Denver, Colorado, recently received an order for 50 Shaw Eclipse Air Hammer Rock Drills, to be shipped to the Copper Queen, Bisbee, Arizona.

THE NATIONAL ORE CONCENTRATION CO. has moved its general office from Milwaukee to 1730 First National Bank Bdg., Chicago. Mr. E. T. Wright will continue to represent its interests in the capacity of president and manager.

THE BEHREND DRY CONCENTRATOR CO. has sold the full rights for manufacturing the Behrend Concentrator in Canada to Barnnell Sawyer of Montreal and Louis P. Jennings of Cobalt. The Canadian company will be called the Behrend Dry Concentrator Co., Ltd., of Canada.

L. S. PIERCE, 1650 Champa St., Denver, Colorado, manufacturer of the Pierce Amalgamator and gold-saving device, recently shipped two of his machines to the Mining & General Supply Co., London; one 25-ton machine to Harron, Rickard & McCone, San Francisco; one machine to Trinity Gold & Timber Co., of California; one 50-ton plant to the Piedmont M. & M. Co., of Georgia; one 20-ton machine to Zarina M. Co., of California; one 40-ton set of riffles to Joshua Hendy Iron Works; two 22 by 48-in. machines to C. H. Smetzer; and two 20-ton plants to the Smuggler-Union M. Co., Telluride, Colorado. This last shipment makes 21 machines in all now in use at the Smuggler-Union mill.

BOOKS RECEIVED.

HYDRAULIC TABLES AND MEMORANDA. By H. D. Jerrett. 12 mo., pp. 144. Published by the author, San Francisco. 1908. Price $1.50. This convenient vest-pocket collection of tables and data for ready calculations in the field will be welcome to those having reconnaissance work to do where access to larger treatises is not possible. It covers all the ordinary ground needed in the solution of problems arising in connection with irrigation and water-supply engineering. For sale by the MINING AND SCIENTIFIC PRESS.

TECHNICAL METHODS OF ORE ANALYSIS. By Albert H. Low. 3d. Ed. John Wiley & Sons. 1908. Price $3. This is not a mere re-print. Much new matter has been incorporated in the text, particularly with reference to aluminum, antimony, arsenic, calcium, lead, magnesium, nickel and cobalt, tin, uranium, zinc, coal and coke. The appendix has also been expanded, bringing the work as nearly up to date as possible. In the effort at keeping abreast of progress in analytic methods, the author has gone so far as to add late notes on the chromate-oxalate method for lead in the form of an inset put into the book after it had been printed. For sale by the MINING AND SCIENTIFIC PRESS.

DEVELOPMENT AND ELECTRICAL DISTRIBUTION OF WATER POWER. By Lamar Lyndon. pp. 317; ill.; index. Price $3. John Wiley & Sons, New York. 1908. This volume deals in a broad way with the inter-relationships of water-power, methods of development, machinery and apparatus employed, and the final use to which the energy will be put. It is not a technical treatise, but is such a review as would prove useful for its suggestiveness to a busy man who had such problems as are involved in the development and transmission of electrical energy presented in connection with other activities. It points out all the elements of the problems, and would serve as a guide to one not a specialist in such work, who desired to acquaint himself with the conditions of modern practice. It contains matter of value relating to the practical management of turbine wheels, and is enriched with descriptions of some of the leading electric power-plants in the world, including the Taylor's Falls-Minneapolis plant, and the Kern river installation of the Edison Electric Co., in California.

ENGINEERING REMINISCENCES. By Charles T. Porter. 8vo., pp. XIII, 355. John Wiley & Sons, New York. 1908. Price $3. For sale by the MINING AND SCIENTIFIC PRESS. Most reminiscences by men who have been more conspicuous as doers of the world's work than as writers about it, turn out to be a mere dreary recital of experiences so intensely personal as to have little interest for those outside the circle within which the author was a familiar figure. Such is far from being the case with the memoirs of Mr. Porter. He has been, in his own person, through brilliant achievement, a large part of the history of the development and perfection of steam engineering in the last half-century. He has been the close friend and collaborator of the great men who have played a leading part in expanding the efficiency of the race by giving it control of gigantic power-machinery. Thus he evokes from his rich experience vivid pictures of such spirits as Charles B. Richards, John F. Allen, Frederick E. Sickels, Sir Joseph Whitworth, Alexander Holley, and a host of others. Moreover, the volume is written with dash and brilliancy, and is brimming with humorous anecdote. It is the kind of book that helps the world to understand and properly measure, as men and as masters of the mechanic arts, those great engineers who have been essential factors in building the structure of modern civilization.

MINING AND SCIENTIFIC PRESS

Whole No. 2497. VOLUME XCVI. Number 22. "Science has no enemy save the ignorant." THREE DOLLARS PER ANNUM Single Copies, Ten Cents.

MINING AND SCIENTIFIC PRESS

Editorial.

SINCE OCTOBER the seven stocks controlled by the seven Guggenheim brothers have appreciated $39,372,832. We get that figure from the *Boston News Bureau*. These seven stocks represent an aggregate capital of $171,416,800. Is it not strange that financiers responsible for such big sums of money should be so eager to make a million or two through the buffoonery of Lawson?

GOLD PRODUCTION in Australia diminished during the first quarter of this year, the total yield being 840,597 ounces, as compared to 875,782 ounces in the corresponding period last year. But New Zealand shows an increase, from 111,465 ounces to 123,325 ounces, so that the net decrease in Australasia is only 35,135 ounces for the quarter. The increase in New Zealand is due mainly to the Waihi mine, in the Hauraki district.

OUR Discussion department is enriched by a letter from Mr. W. A. Caldecott, writing from Johannesburg. This eminent cyanider acknowledges himself to be the 'Viator' who initiated the exchange of opinions in regard to the treatment of an ore containing both coarse and fine gold. To the discussion that ensued Messrs. Philip Argall, E. M. Hamilton, Edward H. Nutter, C. W. Van Law, Edwin C. Holden, E. P. Kennedy, George A. Packard, Walter L. Reid, E. A. H. Tays, and James S. C. Wells have contributed. Some useful information has been elicited. We hope that other men will be prompted to ask leading questions and provoke enquiries of a similarly useful character. This journal is meant to be the medium for such exchanges of ideas and of experience.

FROM NEW YORK we learn that Mr. Henry S. Munroe, of Columbia University, has been elected president of the Mining & Metallurgical Society of America. The vice-presidents are Messrs. Waldemar Lindgren, of the Geological Survey, and C. R. Claghorn, of Tacoma. The treasurer is Mr. W. R. Ingalls, editor of *The Engineering and Mining Journal*, and the secretary is Mr. J. R. Finlay. These are all excellent selections. The choice of president is particularly good, for Mr. Munroe was chairman of the committee on organization and did efficient work in that capacity. As a high type of professional man he is well fitted to be the standard-bearer. The executive committee will consist of the three New York members of the council, together with Messrs. R. H. Richards of Boston and F. Lynwood Garrison of Philadelphia, the idea being to have a committee the members of which are all within easy reach of New York. The first Bulletin will be prepared and issued forthwith; it will contain an introduction

explaining the purposes of the society, the constitution and by-laws, besides the list of officers and members. Arrangements will be made to start discussions during the coming winter, and it is likely that the standardization of cost-sheets, annual reports of mining companies, and the like will be brought forward. Applications for membership are numerous and a high standard is being maintained. On the whole, prospects are most promising for a successful and useful enterprise.

BUSINESS RELATIONS between San Francisco and Mexico will be much improved when we have a good steamship service to the west coast of the Southern Republic and railroads from the coast to the interior plateau. There is a good deal of railroad construction under way, the effect of which will be to connect the Pacific ports of Mexico with the City and with the mining regions of the Sierra Madre. In July the new line from Guadalajara to Manzanillo will be open. We need a better steamship service, and in this connection it is a pleasure to chronicle the fact that the French line of the Chargeurs Réunis has arranged to call at Mazatlan and Guaymas, and later at Manzanillo also. On June 3 the *Ceylan* of this line will sail from San Francisco, and other boats will follow at intervals of six weeks. These vessels are large, commodious, and well equipped for first-class passenger traffic. We hope that this will prove the beginning of a new commercial link between this port and the mining regions of western Mexico.

IN A RECENT issue of the *Nevada State Journal* we find an account of the geology of Jessup that reminds us of the comic treatise on 'The Geology of Jell' written by a learned friend in Columbia University. A newspaper geologist, whose name we forbear to mention, hoping that he may yet learn the evil of his ways, states that "the country is secondary, to all appearance and analysis. From a common level of monotonous basins, internal pressure causing heat, or the residue of nebulous matter seeking a vent, has forced up secondary formations where the crust had the least resistance, resulting in fissures conforming to interior activity, preponderance of weight on the surface and local conditions. In most instances this action was gradual as a growth, denoting the absence of violent or seismitic action, which occurs only as a secondary at rare intervals in the district. These fissures have been filled up with intrusive matter by an upward pressure of soft and silicious elements; have been subjected to heat and rest, admitting of mineral precipitation; fed by extrusive, intrusive and extraneous secretions. Probably long inundation admitted of percolation and infilteration of congenial elements acting as reagents. Do these fissures persist in depth? They should, if our theory is correct. With rest or coolness on the surface, resistance will be greatest on the upward heave at the surface provided the action is slow; this argues a widening of the fissure from the apex down," and so forth. The spelling is unchanged. Two columns of this sort of stuff that will cause a man to doubt the sanity of the editor who allowed such rubbish to get into print. The country may be "secondary" but the geological analysis is primary rubbish swept from a bar-room floor. The basins may be "monotonous" but not nearly so monotonous as the dreary level of balderdash masquerading as science. The fissures may have been "filled with intrusive matter" but never so choked with useless emanations as the columns of the *State Journal*; they may have been fed by "extraneous secretions" but never so overwhelmed with hot air as the readers of that Reno newspaper. The "widening of the fissure from the apex down" suggests a limbo for the disposal of pseudo-scientific rigmarole. Poor old Jessup. The unkindest depreciation of that young mining camp could never have hurt it so much as the publication of the paretic rot of this Reno geologist.

Fundamental Facts.

TECHNICAL RESULTS as quoted in print are apt to be misleading if accepted as representative of average working results obtainable in good average practice. They too often represent the best that has been obtained, or that appears to have been obtained, in selected periods or campaigns, when free from the influence of accidents or difficulty. Students should be prepared to make some allowance, as is the wont of their experienced seniors, for the effects of accident, delay, or the oversanguine enthusiasm of observers, weighers, and the like. The differences between cost, consumption, and yield estimated from short runs are often more favorable than those obtained in the long run, as proved by the logic of stock-taking and the closing of accounts after every expense has been included. What we may call the accountant's cost is generally much higher than that estimated by the foreman or others in charge of the operation. For instance, the copper content of a slag as stated for publication is likely to be less than the actual average because a low assay has been selected for the purpose. The consumption of coke in pyrite smelting also may be that of the official charge-sheet and not that actually used by the men at the furnace, and if it cannot be stated as the average of a sufficiently long period and confirmed by the half-yearly or yearly stock-taking, or such control as the financial interests of the undertaking compel, then it must be regarded as largely ideal. The true test of the amount of copper left in the slag is the sampling and assaying of the dump. The true test of the coke consumption is the quantity the company has paid for, after proper adjustment for stocks at the beginning and end of the financial period. We recall an analysis of blast-furnace gases from the Antipodes that appears to have puzzled an able investigator of metallurgical proportions, namely, Mr. J. W. Richards. The theory of the smelting offered with the analysis was based on ideal conditions and the actuality of practice may have differed from this ideal. More coke or limestone may have been used than was suggested by the ideal case.

There are two fundamental principles upon which

our modern science rests: The conservation of matter and the conservation of force. From so much carbon consumed in a certain way we get so much heat. We cannot get more. From 778 foot-pounds of energy we can get one heat unit and no more. From one pound of any matter we can get no more. We can neither destroy nor create; but only change the form.

Affairs in San Francisco.

FRIENDS in New Zealand and South Africa write asking us what progress is being made in the civic rehabilitation of San Francisco. The question makes us feel ashamed. In New Zealand representative government is in a forward state of development even though the Ultima Thule of democratic ideal has not been reached and in South Africa measures are being taken with a view to a federation of the States and the formation of a political Union. It is not to be wondered that those engaged in mining in those two progressive, though distant, regions should want to know how far San Francisco has recovered from the youthful distempers of representative government. "Watchman, what of the night?" We are compelled to reply that it is dark overhead, a mist makes it dangerous to the wayfarer, the stars are in eclipse, and wise men had better keep indoors. For indeed the outlook is not cheerful. The cause of good government is receiving scant support, the rich criminal walks the streets confidently, Justice is outraged, the administration of Law is disgraced, and Wrong is still defiant.

San Francisco's troubles began with the dominance of the labor union. The men who labor had to combine to protect themselves, for only by the force of combined action could they exact their share of industrial prosperity. Having discovered the power of combination, the labor unions went into politics. They made one of their own men the Mayor of the City and obtained control of the municipal government. The nominees of the labor party proved to be crooks. An exposure followed. On the top of a wave of reformation an honest Mayor and a reputable board of aldermen were elected. An effort was made to punish those who had enriched themselves by bribery and other ways of corruption almost unspeakable. It was found that the merchants of the City and the captains of industry were accessory to the crimes, already partly investigated and exposed. All the power of the men in control of State politics, a large part of the financial power of the banks, a preponderance of the social power of the rich and fashionable people of the City united in an effort to stifle the prosecution of the offenders against civic integrity, as soon as their own friends and associates were implicated. The crooks of the Labor party went into offensive and defensive alliance with the crooks of the Corporation party. The better kind of laboring man saw that if his leaders were crooked, the leaders of the capitalist class were no better, and if money was to be made crookedly, his own leaders might as well have it. The labor unions began the undermining of civic decency in this community; the corporations completed it. Thus the professional man, the average honest laborer, the average honest merchant, the average honest citizen, found himself between the upper millstone of the corrupting corporations and the nether millstone of the corrupted labor unions. That is the plight of San Francisco today.

One incident will suffice to indicate the true condition of affairs. Louis Glass, the vice-president and general manager of a telephone company, was indicted, tried, and convicted of bribing the supervisors or board of aldermen. It was proved that $55,000 of the telephone company's money had been used for bribery and that $7500 was returned by some supervisors who accepted bribes from a rival telephone company, anxious to get permission to do business in the City. In the code of thievery, a man who takes bribes from both sides is not honest, but one who stays bought is a real gentleman! The official—named Zimmer—who took the money from the telephone company's treasury, and handed it to the go-between who paid it to the supervisors, gave evidence before the Grand Jury but refused to testify in the trial of Glass, his superior officer, and was sentenced to jail. This effort to shield crime was hailed as loyalty. Not long afterward, while Glass was still in jail, unable to attend to any business, and unlikely to be able to take part in any of the affairs of the company, the directors of the Pacific Telephone & Telegraph Company met and re-elected Glass second vice-president and Zimmer third vice-president of their company. The directors of this company include some of the "best citizens" of San Francisco. By their action they set the seal of their approval on crime, they honored a man duly and properly convicted of a felony, and they asserted their right to flout Justice.

Meanwhile eight or nine trials have followed and all save one have ended either in acquittals, in disagreements of the jury causing a mistrial, or in reversals of the verdicts of the lower court by appeal to the Appellate and Superior Courts. On the whole, the efforts of the District Attorney and of the men in his office have failed, except in so far as they have exposed the true condition of affairs. The judges of the Superior Court, before which the trials take place, are chosen in a political election and owe their position to political considerations in a State where the political power is in the hands of a railroad company. In fairness to the particular judges before whom these trials came, it must be said that they were partial to the prosecution, even though honestly. They exhibit the defect of the system under which they are selected, by giving rulings that are open to reversal in the higher courts, and such reversals have already destroyed much of the work accomplished, with temporary success, by the prosecution acting for the community. The District Attorney is a school-teacher who by the sport of politics became nominated to his important office and held it because of his honesty, but not by reason of any special ability. He has been assisted by Francis J. Heney, a fearless advocate and the leader of the

forces of the prosecution, which has been financed, not by the City, but by a private citizen and an honorable man named Rudolph Spreekels. It is likely that the City will relieve him of the burden of finding money for the defence of its integrity. But what a topsy-turvy condition of demoeraey! Save for the public spirit and courageous purpose of a handful of men it would have been enough to depress the fondest believer in the representative form of government. And through it all the power of the press —the supposed palladium of our liberties—has been at first covertly and then openly in favor of the corrupters even when it was not frankly for the corrupted. Journalism has been hired to do the meanest tricks, journalism has been paid to do the most servile duty, journalism has proved itself the friend of crookedness and thievery.

The press has been prostituted, and even the profession of the law has played into the hands of wrong-doers. Seeing that the District Attorney was a poor lawyer but honest, seeing that the City's real advocate was over-worked, harrassed, and open to criticism in some respects, might it not be supposed that scores of the ablest lawyers in the community would have volunteered their services in the cause of the City and have given their counsel to their legal brethren who were making such a splendid uphill fight. Not at all! We are sorry to tell our friends in New Zealand and South Africa that the leaders of the bar, the legal talent of the community, the great brains of a noble profession were given to the cause of wrong, to the protection of the criminal, to the subversion of right. In this City at this time the profession of the law is largely devoted to the suppression of Justice and to the evasion of Law; nine out of every ten of the leading members of the bar are busy showing rich men how to do wrong and yet evade arrest.

Even trial by jury has been undermined. Most of us have believed that a jury was an epitome of public opinion and that, come what might, a jury could be relied upon to deal justly. But even in this department the seed of corruption has been plentifully sown. The Grand Jury, before which a suspect is called before indictment, is selected by the Judges of the Superior Court; each of the 12 judges chooses 12 men, making a list of 144 names out of which the Grand Jury of 18 is chosen. Some of the pals and partners of the crooks were placed upon this list and it can only be guessed how and why. In selecting the petty juries, the procedure is different. In the counties of California it is the duty of the chairman of the board of supervisors to select names to be placed in the jury-box, but the sheriff and clerk of the Court must be present. In the City, the judges of the Superior Court select the names to be put in the box; the men chosen must be taxpayers and it is usual for the selection to be made from the precinct register. Each of the 12 Superior judges selects 200 names and these 2400 names are placed on slips of paper in the jury-box. As a matter of fact the selection is apt to be deputed by the Judge to the Clerk of the Court and by him to his deputy, so that in one way or another an opportunity is given for those interested to stuff the box with the names of men amenable to corruption. The railroad company, the street railway company, and other corporations having frequent damage suits for accidents, find it profitable to maintain an organized secret service devoted to the doctoring of jury-boxes, the corrupting of those selected, and the obstruction of those who may prove obdurate. One of the crooks, who was also the main go-between in the bribery of the municipal officers, and the political boss of the City, is named Ruef; he is a Jew; it was more than a coincidence that every other man drawn from the panel in the recent trial was a Jew or a saloonkeeper, or both. In the trial of the ex-Mayor fully one out of every three of the men drawn proved to be saloon-keepers or cigar-dealers who sold pools on the races, that is, men likely to be involved in such illegal acts as would keep them under the thumb of the police. Through the police force, which was headed by a crook and is now headed by a well-meaning duffer, it was easy to control these possible jurors. Further, the men on the list are called to the Court by the Sheriff or his deputy; it is easy to notify certain men to be absent when the summons to duty arrives, and to inveigle others away. Thus, and in other ways, it is possible to fix the jury. In the last case tried, two ex-convicts were actually impanelled and provisionally accepted as jurors, and it was only by good luck that their record was ascertained by the District Attorney's office before they were sworn in to try the case. There is no doubt that the lawyers for the defence knew the antecedents of these men and thought it proper tactics to get them on the jury in aid of their client. And to be fair, it is proper to say that even the prosecution will wink at the selection of a juror whom they know to be biased, if the bias be toward their own case. In combating the trickery of the criminal and of his criminal attorney, there is a tendency to fight the Devil with fire, instead of a hand-grenade.

The gentlemen in New Zealand and South Africa will not find much encouragement in this picture; they may feel prompted rather to adopt the beneficent despotism tempered by industrialism of Mexico or the military autocracy modified by revolution of Colombia than the corrupted government "by the people and for the people" in this American city of San Francisco. And yet it may be well for them to wait and watch. It is useless to promise and it is vain to predict. We still have faith in the uncorrupted core of essential manhood that makes for American progress. Our City will yet redeem herself—she *must*. San Francisco stands at the gateway of Occidental civilization, facing the re-born world of the Orient. Is the Caucasian to confess himself played out? Shall a Chinese mandarin or a Japanese merchant point to our corporation officers as types of indirection, inicivism, and graft? Not long ago a Mexican of the *plebe* class visited San Francisco and on his return to Zacatecas, he told an American mining engineer that San Francisco was too dangerous a place for him and he had decided to come back to Mexico! Anyone who has lived in Mexico will appreciate the sardonic humor of this true story.

Personal.

R. A. F. PENROSE is here.

RALPH NICHOLS is in Idaho.

GEORGE A. PACKARD is in Arizona.

W. H. WEED is in British Columbia.

F. J. H. MERRILL is here from Nogales.

W. E. THORNE is at Redding, California.

W. A. PRICHARD is here from Mexico City.

THOMAS RICKARD was at Goldfield this week.

H. N. TOD is at Ballarat, Inyo county, California.

H. C. WILMOT, of Butte, is here on a brief holiday.

F. R. WEEKES is now in Florida on professional work.

FRITZ WOLF is in San Francisco from Mazuma, Nevada.

W. J. SHARWOOD has returned to Lead City, South Dakota.

JOHN W. PROUT, of Denver, was lately at Globe, Arizona.

A. H. ELFTMAN, of Tonopah, was in San Francisco recently.

J. MORGAN CLEMENTS, was married at New Haven on May 8.

H. KILBURN SCOTT is on his way from London to Nova Scotia.

O. B. PERRY passed through San Francisco on his way to Dawson.

AUBRY RYLAND is superintending a lease at Seven Troughs, Nevada.

LYMAN BRIDGES is manager for the Acme Mining Co., at Tucson, Azizona.

J. PARKE CHANNING is expected in New York, on his return from Europe.

CHARLES D. KAEDING, of Goldfield, came to San Francisco from Los Angeles.

HENRY BRATNOBER is at Seattle, preparing to go to the Seward Peninsula.

GEORGE A. SCHROTER has gone to Nevada and will proceed shortly to New York.

RICHARD SNELL sailed for Salvador on May 22, to be assayer at the Devisadero mine.

F. PERCY ROLFE, manager for the Keystone mine, in Wyoming, is on a visit to London.

FRANK OLIVER has returned to Goldfield, after a short holiday in southern California.

R. B. NICOLSON, the manager of the Ivanhoe mine, Kalgoorlie, is expected in London.

D. M. RIORDAN is here from New York, on his way to the Bully Hill mine, in Shasta county.

R. S. RAINSFORD, manager of the Argonaut mine, at Jackson, California, was here this week.

W. A. HEYWOOD has concluded his visit to Namaqualand, South Africa, and is now in London.

PATRICK KELLY, from Karangahake, New Zealand, was in San Francisco, on his way to Nevada.

FRANK H. PROBERT has been appointed consulting engineer to the Superior & Boston Copper Company.

EDWIN H. DAVISON, until recently in charge of mines at Fundicion, Mexico, is visiting San Francisco.

H. W. DUBOIS, of Philadelphia, is on his way to British Columbia. Later, he will proceed to Dawson.

T. SKEWES SAUNDERS is now superintendent of the Teziutlan Copper Mining & Smelting Co.'s mine at Ejutla, Mexico.

LOUIS A. WRIGHT is general manager and F. C. ALSDORF is superintendent for the Miami Copper Co., at Globe, Arizona.

E. H. SIMONDS has removed to Room 416, Crocker Bdg., San Francisco. His laboratory remains at Oakland, California.

HENRY CRUMM has been appointed to make a special examination of the Tonopah Extension mine, at Tonopah, Nevada.

CARNEY HARTLEY has opened an office at 204 Empire Bdg., Denver, and will design, install, and operate placer mining machinery.

W. R. CRANE, lately in Columbia University, has been chosen Dean of the School of Mines and Metallurgy of the Pennsylvania State College.

W. W. WISHON has returned to Los Angeles after making an examination of the properties of the Tucson Consolidated Copper Co., at Tucson, Arizona.

E. MCCORMICK has assumed the management of mines and smelter of the National Mining & Smelting Co., with headquarters at Deming, New Mexico.

EDWIN C. HOLDEN has accepted the appointment of professor of mining engineering in the University of Wisconsin and has retired from the firm of Hill, Holden, & Irvine.

J. S. HAMMAN and C. E. JAMISON have formed a partnership as mining engineers and metallurgists, and have opened an office at 1034 Central Bdg., Los Angeles. Mr. Jamison retains his connection with the De La Mar mines.

General Mining News.

ARIZONA.

GLOBE COUNTY.

The Old Dominion is planning to carry the water of Pinal creek through 5000 ft. of flume to Steads' ranch, to prevent its seepage into the mine. The water pumped from the mine will be carried to the main flume.

GRAHAM COUNTY.

The output of the Arizona Copper Co. for the month of April was 150 tons of bessemer copper, and of the Shannon Co., 725 tons.——The Home Copper Co. has let a contract for driving the Lillian adit 1500 ft. through Buzzard Shadow Mtn. The adit is in 700 ft. and has passed through several streaks of rich ore. Another gasoline hoist will probably be put in the adit and sinking started on some of the veins. The Home company has also let a contract for sinking the shaft on the May mine 300 ft. deeper.

MOHAVE COUNTY.

A rich strike is reported in Boulder canyon, 10 miles below Bonnelli Ferry. The vein is said to be 10 ft. wide and to show an outcrop more than a mile in length.——The Yucca Cyanide M. & M. Co., at Cedar, lost their assay office by fire last week.——It is reported that the Aztec Turquoise Co., at Mineral Park, will start work soon. Two other companies are now working.——The New London mine, near Cerbat, is working a small force sinking a new shaft.

PINAL COUNTY.

The Copper Creek Co. has 9 six-horse teams hauling machinery and lumber to Sycamore Flats, in Copper canyon, and it expects to have its concentrator running by July 1. The townsite is being laid out.——It is rumored that a 40-stamp mill is to be built on the Mohawk property at Mammoth. A cross-cut has recently been completed on the 350 level, and another started on the 400. When the latter is completed stoping will be started.——Fifteen men are employed in developing the Leatherwood property, in Catalina Mtn.——Harner & Hand report a strike of a 6-in. vein of gold ore which it is claimed will assay $100 per ton, with some specimens running as high as $1200.

CALIFORNIA.

NEVADA COUNTY.

(Special Correspondence).—A small vein of rich ore has been struck in the hanging wall in the 500 level of the Idaho-Maryland. Work is under way to determine the extent of the discovery, and men are being added as rapidly as they can be used. The main vein has widened from 6 to 10 ft.——Rich gravel and a 16-in. quartz vein have been discovered on the Kohler ranch, a few miles northwest of Grass Valley.——Joseph O'Keefe and W. T. Crase have leased the South Idaho mine and will sink a new shaft at some distance from the old workings.——A deposit of rich gravel has been developed on the claim of the Weare Bros., seven miles north of Banner Mtn. The channel is 200 ft. wide and 40 ft. deep. An adit will be driven to open up the deposit. Considerable black sand carrying gold is in sight.——A good body of high-grade ore has been struck in the adit of the Central Consolidated mine. The quartz contains sulphides and some free gold.——The working force at the Brunswick has been reduced. Most of the ore is coming from the 900-ft. level.——It is reported that the Norambagua mine will be re-opened and worked by Shasta county mining men, who recently inspected the property.——Another good ore-shoot has been struck at the Red Ledge claim. The owners are pushing development.

Grass Valley, May 26.

TEHAMA COUNTY.

The Bonanza mine in Harrison gulch, operated by the Victor Power Co., has received a 15-hp. hoist, 500 ft. of cable, shafting, buckets, boilers, etc., and they are now being hauled to the property. The shaft is now 100 ft. deep and will be sunk 400 ft. deeper.

TRINITY COUNTY.

The Nash mine, on Coffee creek, has been leased to James W. Furness, and not to Gordon Abrams as stated in our issue of May 9.

TUOLUMNE COUNTY.

(Special Correspondence).—H. W. Gendar, who has taken a bond on the Anaconda mine, near Columbia, is sinking the shaft from the 112-ft. level, using electric power.——The El Oro mine (formerly the Oakland) will start its mill about June 15 with 5 stamps.——The United Mines Corporation, which controls a group of claims along the north fork of the Tuolumne river, is installing the equipment for its new 20-stamp mill. The mill will have a capacity of 120 tons per day, which will be increased if results warrant. The shaft on the New Albany, one of their claims, is now down 700 ft. and will be deepened 300 ft. more. An adit on the Lady Washington, another of their properties, is being pushed forward. The company uses electricity, generated by water obtained through a flume from the north fork of the Tuolumne river.——The plant of the Sierra Lime & Cement Co. is being rebuilt, and shipments of lime to San Francisco will be resumed.——P. H. Craven, inventor of a slime-table, is building an experimental plant at the Eagle-Shawmut.——Sinking is to be resumed at the Harvard shaft, which is now 800 ft. deep. Eighty men are employed and 40 of the 60 stamps are dropping. Numerous minor improvements are being made around the mine.——The Black Oak has been unwatered down to the 200 level.——A head-frame is being erected, a compressor installed, and other machinery put in at the Gold Crater, in the vicinity of Knight creek.——The Springfield Tunnel Co. has received a new engine and boiler.——The Imperial, near Jacksonville, has temporarily suspended operations, pending the collection of an assessment from the shareholders.

COLORADO.

GILPIN COUNTY.

The St. Louis mine, in Winnebago hill, is to be worked by New Orleans people under a lease and bond. There is now a 100-ft. shaft on the property, but the new company expects to sink another.——The Golden Flint mill (formerly known as the Rollins), at the head of Gamble gulch, was started last week on ores from the Golden Flint mine. A new boiler and a Standard table have been added to the mill.——The Iroquois Co. has let a contract for sinking its main shaft 100 ft. deeper and the work has started. When this work is completed the shaft will be 220 ft. deep and from there cross-cuts will be driven to develop the mine.——Four carloads of ore from the Champion and the Lone Star mines, in the Phoenix district, were received at the Fifty mill, in Black Hawk, last week. The ore came by way of Denver over the Moffat road.

GUNNISON COUNTY.

It is reported that John Patterson, who recently purchased the old smelter dump at Gunnison, plans to build a plant to treat the slag. The dump will assay $13 per ton, and is estimated to contain 75,000 or 100,000 tons.——The Blaine has undercut a large body of ore on the Alice claim, at Guthrie, at a depth of 125 ft.——The Black Queen management reports that the ore recently cut at the 70-ft. level has improved, and that a car of shipping ore will be sent out soon. The mill is running steadily.

LAKE COUNTY.

A force of men is at work on the old Starr placer property, under the Midland trestle west of Leadville, and it is announced that much ground in that vicinity will be washed during the summer. It was in this vicinity that the first important discoveries of the Leadville district were made, and the Starr property itself has already yielded several millions of dollars in mineral wealth, all coming in the form of pure gold gathered in fine particles from the dirt and gravel.——R. W. Foot will start work soon on the Wellington group, using electric power to sink a shaft.

SAN JUAN COUNTY.

The Hamlet mill is closed down pending the renewal of the rolls, but will be started again as soon as the work is completed.——It is rumored that the Polar Star, on Engineer Mtn., will be re-opened by Jack Carroll, after years of idleness. Large amounts of high-grade ore were taken from this mine in early days.——The Hercules Con. M. & M. Co. is working three shifts in its recently enlarged and remodeled mill. Regular shipments, averaging a carload per day, are being made.

SUMMIT COUNTY.

The second of the big dredges of the Colorado Gold Dredging Co., near Breckenridge, was started last week.——The Wire Patch mill, near Frisco, is running full-blast, treating the product of the several neighboring mines. The Wire Patch uses electrical power entirely, and is at present working two shifts.——The Reliance Gold Dredging Co. has been recently organized to work a large block of placer ground which it has secured near Breckenridge.

TELLER COUNTY.

H. L. Bull, who has leased the Fluorine property on Copper Mtn., is planning to open the old cyanide mill on that property.——Rains & Co. have uncovered a body of ore 2 ft. wide assaying $100 per ton, in the 400-ft. level of the Anchoria Leland, on Gold hill.——The Big Four leasing company on the Carbonate Queen recently shipped the last carload from the dump on that property.——The Old Gold property, on the west side of Beacon hill, has been leased to Mulvaney & Ganson, who expect to work it above the 400-ft. level. The Old Gold is flooded below that point, and the conntry rock is so dense that the water does not seep into the El Paso tunnel, which is 200 ft. lower.——The Isabella is shipping from 75 to 100 tons per day, coming from four different levels—the eighth, ninth, tenth, and eleventh. In addition, the cyanide mill is treating 100 tons of tailing per day. Two shifts are at work.

IDAHO.

IDAHO COUNTY.

(Special Correspondence).—The Buster 10-stamp mill is running night and day. Gold is saved on amalgamation plates and in cyanide tanks, while about 35 tons of concentrates monthly are shipped to Tacoma.——The Butte-Orogrande mine, on Crooked river, is operating its 20-stamp mill. About 40 men are employed.——The strike on Four Mile creek made some time ago, which showed tellurides of gold, has stimulated a number of locations there, but snow covers the ground and nothing can be done for weeks.——The Golden Crown, the Mountain Con., and the Del Rio mines, all near Elk City, have resumed development work.——A contract has been let to drive an adit on the Laura B. property, on Crooked river below the Thunder Mountain mine.

Elk City, May 23.

SHOSHONE COUNTY.

(Special Correspondence).—The electric hoist of the Hecla is now completed and mining will soon be resumed. The hoist is designed for a depth of 2500 ft. and a load of 3000 lb.——The Snowstorm is shipping ore at the rate of 500 tons per day, and it is understood this output will be increased by 200 tons within the month of June. Development in the long No. 1 adit is being pushed. With the improvements installed during the recent depression the Snowstorm is now enabled to operate at a cost of $1 per ton, and is said to be earning a good profit. More ore is now being shipped than at any time during the boom in copper. ——The East Snowstorm is driving a 600-ft. cross-cut from its 900-ft. main adit to tap what is said to be the Snowstorm vein. The vein is carried for 3000 ft. on the East Snowstorm property, and indications in development are said to promise a formation similar to that of the Snowstorm. Small assays in gold are constantly being found. ——The Rex, which was recently closed down, will be re-opened under a new management, B. M. Francis having retired. Debts of about $35,000 will be paid off at once, and the mine will be developed extensively before the mill is again put in operation. Clean shipping galena has been found in the drifts from the foot of the winze. This winze will be sunk 200 ft. deeper, where it is thought the shoots found above will meet the solid vein. During the short run 20 carloads of ore were sent to the East Helena smelter.——The drift on the Black Bear Fraction vein has now attained a depth of 70 ft., and during the last 40 ft. galena of increasing richness made its appearance. It will take 150 ft. more to come under the upper winzes, to which raises will be extended. A mill will be installed this summer.——The Tamarack & Chesapeake has filed its annnal report, which shows a net loss for 1907 of $24,941. This is due to heavy development which has been carired on.

Burke, May 25.

(Special Correspondence.)—An important strike is reported from the Paymaster mine, about a mile east of Ward-

Map of Idaho.

ner. The ore was uncovered in the upper workings after following a lead for over 100 ft. The ore is rich in copper and lead and the vein is 4 ft. wide. A mill will be built. ——The Stanley Con. M. & M. Co. has started a suit against the Hercules Mining Co. for the recovery of $27,500 damages. The suit is based on the ground that the Hercules has polluted the water-supply of the Stanley mill.——An assessment of ½c. per share has been levied on the capital stock of the Big Divide Mining Co., payable on or before June 8. ——It is expected that the Panhandle smelter will start about June 1. The management has been promised a good supply of local ore, but will treat nothing but silver, lead, and gold ores at present. The smelter will begin with a supply of about 250 tons of ore per day, and this amount will be gradually increased until the full capacity of 500 tons is reached. The copper equipment will be completed about October.——The Butte & Coeur d'Alene mine, near Mullan, is beginning to take an important place in the ranks of the promising dividend-payers. The property has just been the subject of a close investigation by the prin-

cipal stockholders and owners, and it is believed that the mine will commence shipments in the near future. It is claimed that the ore-shoot is a continuation of the Hunter vein. The face of the adit is in 670 ft. and will be run 500 ft. farther. The men are driving west on the vein recently cut and at the same time the cross-cut is being pushed forward. The company is financed for at least another year.——A group of financiers from Missoula has taken an option on the Mineral Farm property, in the Mullan district. The terms of the deal are not made public. The first payment has already been made and the option calls for a settlement in full before the end of the month. All the controlling stock has been placed in escrow with the First National Bank of Spokane.——Operations have been resumed in the Little Mint property on the Montana side of the divide. The adit will be completed in about three months. The property has a good outcrop of gray copper. ——The annual meeting of the Ruth Con. M. & M. Co. has just been held, and the old board of directors has been re-elected for the ensuing year. The whole face of the tunnel is in pay-ore, and the force of men at the property will be increased soon.——Development work has been resumed at the Sister property, between Wallace and Burke. The men are engaged in driving on the vein. An assessment of two mills per share has been levied by the company. ——An official statement has been issued to the effect that the force of men on the Lucky Calumet property, near Mullan, is to be doubled as soon as the snow has cleared sufficiently to allow transportation of provisions. Ten men are employed at present.——A gold nugget worth $240 has recently been found on property owned by Blaine Ward on Trail gulch, between Wallace and Murray.——During the past two weeks no development has been done on the Advance, near Mullan, on account of the air-pipe running out. A new pipe is being put in and as soon as it is in place the driving of the adit will be resumed.——An assessment of one mill has been levied on the stock of the Wonderful company, payable June 24. The proceeds will be applied toward the continuation of development work.——Another strike is reported from the property of the Tiger-Poorman mine at Burke. This strike was made in the 1300-ft. level and at a distance of about 900 ft. from the portal of the tunnel. The vein has been found to split, one section consisting of about 5 ft. of high-grade ore and the other of about 7 ft. of good concentrating ore. The full extent of the latter orebody has not yet been ascertained. None of the ore is being shipped. The mine is one of the properties of the Federal Mining & Smelting Company.

Wallace, May 25.

NEVADA.

ESMERALDA COUNTY.

It is reported that the townsite management at Rawhide Junction, at the head of Walker lake, has let a contract for a 100-ton mill, on which work must be started within 30 days.——The Daisy, at Goldfield, has broken ground for its new mill, and will when it is completed treat its own ores. The main shaft is being enlarged to a three-compartment.——An orebody 14 ft. wide, which it is reported assays $20 per ton, has been uncovered on the property of Johnny Frank a few miles west of Lida.——The St. Ives has during the past week struck a body of quartz ore on the 500 level which assays as high as $356. The extent will not be known for a week or ten days.——Work has been resumed on the Pittsburg-Nevada property, in the southeastern part of the Goldfield district.——Lee Garrett has sold his interest in the Goldfield Con. Mining & Leasing Co.'s lease on the Kendall. The purchasers are Vahrenkamp & Dorsey, who will put 30 men to work at once. The output is expected to reach 50 tons per day, and will be treated in the Bonnie Clare mill.——The production of the Goldfield mines for the week ending May 22 was 2439 tons, valued at $211,537.50. The Tonopah mines produced 6110 tons, estimated to be worth $120,000.

HUMBOLDT COUNTY.

The Standard group of six claims, adjoining the Eclipse on the west and north, has been purchased by J. M. Harman, who will at once develop the property.——The Michigan Co., operating on the Thor ground, between Seven Troughs and Mazuma, has ordered a 9-hp. pump to handle a large inflow of water at the 175-ft. level. They have been compelled to suspend operations pending the arrival of the pump.——A recently announced discovery of rich ore in the East Humboldt range has caused a rush of prospectors and investors. Tiptop, the centre of the excitement, is 12 miles southeast of Mill City, on the Southern Pacific.

LINCOLN COUNTY.

The Deeping Eldorado Gold Mining Co. has been incorporated to take over and work the Humphrey group of 17 claims, a mile north of the Wall Street mine, in Eldorado canyon. The property has several shafts, the deepest of which is 170 ft. The ore is said to be free-milling and bears considerable manganese.——The building of the Duplex cyanide plant at Searchlight was destroyed by fire last week. The loss also includes an assay outfit and $5000 worth of precipitates, 50% of which it is thought may finally be recovered. A good orebody has recently been uncovered at the 400 level of the Duplex mine, which it is claimed is 12 ft. wide and shows 2 ft. of shipping ore.——The new machinery for the smelter at Rich Hill, near Searchlight, has arrived and is being installed.

NYE COUNTY.

The West Extension, at Rhyolite, plans to sink a new shaft and make it the main working exit of the mine. It is reported that one foot of ore on the foot-wall of the south drift of the West Extension will average $5000 per ton.——It is reported that N. Paulsen, who is leasing on the Round Mountain Antelope property at Round Mountain, is planning to build a mill at once.

WHITE PINE COUNTY.

Regular shipments have begun from the Veteran mine of the Cumberland Ely to the big concentrator at McGill.—— Ore which it is claimed runs 75% lead has been uncovered at Duck creek, eight miles north of McGill.——Final payment of $10,000 has been made by S. A. James on the Rarus group of claims, southwest of Lane City. The property will be developed at once by means of a 100-ft. shaft.——The clearing of the Alpha shaft on the Giroux is completed and sinking has started. The shaft will be put down to the 1100 or 1200 level, at which point cross-cuts will be driven. The mill will be ready to start within the next 10 days. When completed it will use only the water pumped from the shafts of the company.——The Francis M. shaft of the Ely Bonanza Copper Co. was flooded with water last week to within 100 ft. of the surface.

NEW MEXICO.

SOCORRO COUNTY.

(Special Correspondence).—The Last Chance mine, at Mogollon, is maintaining its usual production of 60 tons per day, making it the largest producer of gold and silver in the Territory.——Cleaveland & Weatherhead are sinking the Deadwood shaft 200 ft. deeper, working three shifts and machine-drills. This property joins the Last Chance on the south, and its new orebodies seem to show that the Confidence Last Chance vein has frequent and regular orebodies for over a mile along the strike.

Mogollon, May 23.

UTAH.

JUAB COUNTY.

Work has been resumed at the Lower Mammoth mine. A small force is re-lining the shaft and repairing the machinery.——The repairs at the Raymond are completed and work will probably be resumed next week.——The McKinley management is receiving bids for the sinking of a 100-ft. incline shaft from the 400-ft. level.——Shipments of ore from the district amounted to 64 carloads for the week ending May 23, the shippers being as follows: Centennial Eureka, 52; Bullion Beck, 3; Eureka Hill, 4; May Day, 5.

SALT LAKE COUNTY.

The Butler Liberal Co. has resumed work at the Butler shaft and at the Jacobs Tunnel, employing three shifts at each.——The Boston Con. expects to increase shipments from the porphyry workings to 2000 tons per day. One thousand tons of porphyry and 300 of sulphide ore are now being shipped.——The Bingham-New Haven is changing its aerial tramway to the opposite side of the canyon. This change is made necessary because in the future the ore will be taken from the lower adit.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence).—The Colville Mining & Smelting Co. expects to start its two rotary furnaces at Park City in a short time. These were taken in on sleighs last winter, and the work of installation is about completed. It is reported the company is buying another group of claims in the district.——The Mineral Hill Tunnel & Copper Mining Co. has driven an adit 1300 ft. long, from the face of which they expect to drive laterally about 700 ft. to strike the Minnehaha workings.——A vein has been encountered in the Handspike mine, on the north side of Umatilla gulch, in Keller district, which surpasses anything yet found on Tollaman Mtn. It is an east-west vein, 4 ft. wide, and assays over $50 per ton in gold, silver, and copper.——The No. 3 adit on the Copper King mine is in 581 ft. No ore appearing at the face, a raise, started 110 ft. back from it, revealed the foot-wall of the vein at 20 ft. above the roof. The raise was continued 7 ft. in solid hard iron-sulphide ore, bearing gold, silver, and copper. A statement was made that the vein is 50 to 60 ft. wide at that point, but there is no way of telling, or even estimating, the width at any point below the first level. In the raise the vein appears to be pitching very flat. The adit is being driven ahead to determine the pitch and strike.——The adit being driven at the Park City by the Colville Mining & Smelting Co. to intercept the Mountain Boy vein, is in 756 ft. It was expected the vein would be reached at 725 ft., but the formation (silicious limestone) has twisted from 40 to 50°, and it is now suspected that the vein has made an unexpected turn.——The Hercules tunnel has been driven 470 ft. and is now running parallel with the vein. A cross-cut from the face has penetrated the vein and some good ore well impregnated with chalcopyrite and galena has been developed. The cross-cut is being continued to ascertain the width of the vein.——The Department M. & M. Co. is planning to start work on an extensive scale on the Empire mine, in the Curlew district.——The B. C. Copper Co. is expected to resume work on the North Star and Washington claims about June 1, after a short period of idleness. ——The Railroad mine has several carloads of ore on the dump, which the company will ship as soon as arrangements can be made with the smelter people.

Republic, May 23.

STEVENS COUNTY.

(Special Correspondence).—The Robena M. & M. Co. has driven over 50 ft. of its lower adit and expects to drive about 400 ft. farther, to tap the vein at a depth of 162 ft. A quartz vein in the upper workings is 6 ft. wide and bears galena which may be concentrated to advantage. The second carload of ore is ready for shipment and will be sent to the Tacoma smelter.——A quantity of iron pipe and other supplies has been purchased for the Paymaster mine. Orders have been received from the company to push work as fast as possible, and unusual activity is expected.——In Metaline district the Calumet & Hecla Mining Co. has a group of eight claims which is traversed by two separate veins, about 800 ft. apart, that yield silver, lead, and zinc. There is a large quantity of ore on the dumps, and the stopes are sufficiently opened to run a 100 ton mill for some time. The company will erect a concentrator, much of the machinery for which is already on the ground. A saw-mill will be set up for cutting the lumber for the mill on the spot. ——The North Star mine, on First Thought hill, has let a contract for driving a 300 ft. adit.——At the Trophy mine a 200-ft. adit contract has just been completed.——The Silver Star mine, on Onion creek, in the Northport district, has lately uncovered an 8-ft. body of rich silver-lead ore.——The Spokane Lead Mines Co., at Metaline, expects to be concentrating ore in its mill early in June.——The Panhandle smelter is contracting for the richer lead ores of the Metaline district.

Metaline, May 23.

CANADA.

BRITISH COLUMBIA.

(Special Correspondence).—The western branch of the Canadian Mining Institute concluded its recent convention, at Rossland, with a visit to the mines of the camp. The managers of the large mines accompanied the party on its trip, and all members express themselves as well pleased with their stay in the Golden City.——The Jumbo mine will start development within a short time.——The shaft of the Centre Star, the heaviest shipper, is now down to the fifteenth level, 2100 ft. from the collar. Owing to the good showing, the shaft will be sunk still deeper. Rich ore is still being produced at the War Eagle.——A carload of ore was shipped out from the Blue Bird during the week. Work is being executed in the South Belt with some of the fervor and hope of old days. The Monday, near the Blue Bird, has been leased by John Brokenshire and associates, Mr. Brokenshire having sold his interest in the Blue Bird lease.——The business interests of the Boundary are in high spirits over the resumption of work by the B. C. Copper Co. and the anticipated starting up of the Snowshoe, with a faint hope that the Dominion Copper Co. may fall into line at an early date. Conditions are improving at the Copper company's properties, and before 30 days have passed they will be in a position to produce 2000 tons of ore per day and turn out over 1,500,000 lb. of blister copper. ——The plant of the Dominion company is being kept in readiness to start, but no such instructions have been received from headquarters.——The Crescent, in Skylark camp, shipped a 30-ton car to Trail smelter last week.——The plant of the Canada Zinc Smelting Co. will begin operations June 1. The capacity will be 20 tons per day. The plant is electrically operated and will consume 1000 hp., which will be furnished by the West Kootenay P. & L. Co. ——A rich strike has been made on the Granite-Poorman, near Nelson. The old vein has been uncovered and shows ore rich in gold.——A car of ore shipped from the Slocan Sovereign milled 90 oz. silver and 62% lead.——At the Giant mine, Golden, an up-to-date Elmore oil-process concentrator has been installed. This new-style plant will no doubt be more successful than the first machines were. ——It is the general opinion that the lead bounty will be extended, although nothing has been given out yet. One favorable feature for this continuation is that there is yet enough of the original grant unearned to run for six years, at the present rate.

Rossland, May 25.

MEXICO.

The Compañia Explotodora de Jalisco was organized on the 28th of April to explore and develop some 200-odd pertenencias in the State of Jalisco, of which 82 are in the heart of the Hostotipaquillo district.——The Mexican Mines-Prospects Co. has acquired a controlling interest in the Compañia Explotodora de Jalisco and the entire administration of the company has been placed in the hands of the management of the Mexican Mines-Prospects Co. Some prospecting work has already been done and a small tonnage of high-grade copper-silver ore has been extracted incidentally, but no attempts at extracting metal will be made until a thorough exploration of the properties demonstrates the best method of economically developing and extracting the ore.——The Real del Monte y Pachuca paid a dividend of practically ₱100 a share, aggregating ₱255,400, and the early payment of another large dividend is rumored. The new Guerrero mill has been placed in operation, which gives the company an additional daily capacity of 300 tons.—— New hoisting and pumping machinery has been ordered for the Buenaventura mine in the Sahuayacan district of Chihuahua.

Special Correspondence.

LONDON.

Aluminum Production and Prospects.—Troubles of Clitters United. —Great Boulder Proprietary.

The present low price of aluminum is causing the shareholders of English producing companies some uneasiness. For many years the price was not far from £150 per ton, and it was only in 1906-07 that the price boomed. During the winter of 1906-07 the average price was £200 per ton. Many people argued that the claims of aluminum were at last being recognized in the industrial world, and that the increased demand was due to the preference given to this metal over steel and copper. It was mortifying, therefore, to find that aluminum slumped with the rest of the metals during the summer and autumn of 1907; in fact, sunk proportionately more than its rivals. At the present time the price is between £80 and £90, and the producers admit that the demand is very slack. In some quarters it is stated that this slump in prices is not due solely to industrial inactivity, but to a policy of cutting inaugurated by the German and American producers, who desire to cripple the two English companies. The German and American producers have had the start of the English by a good many years. In fact, the English industry is only in its infancy. It is a plausible theory that the cut is intended to damage them just at the time when their installations on a large scale are approaching completion. On enquiry, however, I do not find any evidence of such a policy being pursued, and the directors of the English companies say that they are not aware of any competitive cuts. There is a general impression among people who are good judges that the days of high-priced aluminum are over, and that about £100 or £120 will be aimed at by producers as a maximum price. There is a rumor afloat in metallurgical circles to the effect that some producer has a process ready for active work whereby it is possible to use a cruder raw material; that is to say, that the refining is to be done after smelting, instead of before. If this be true, and I cannot say whether it is or not, the cost of production should be greatly reduced.

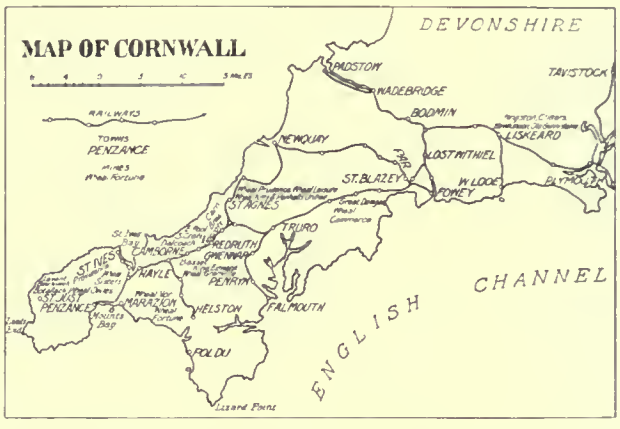
The two producers of aluminum in Great Britain are the British Aluminum Co. and the Aluminum Corporation. It is a Hibernianism to say that the latter is a producer, for their works are not yet completed; but let that pass. The British Aluminum Co. has been in existence for years. At the present time it is producing at Foyers and at a temporary plant at Kinlochleven, both in Scotland. The permanent works at Kinlochleven were to have been ready this year, but delay on the part of the contractors has occurred, and another year will elapse before they are completed. The company is also building works at Stangfjord, Norway, and Orsieres, Switzerland. When all are completed the total horsepower applied will be 70,000.

The other company, the Aluminum Corporation, is building works at Newcastle on Tyne, and in Carnarvonshire, Wales. The first named immediately adjoins the generating station of a big electric supply company which uses local coal. The Carnarvonshire works will be at first supplied by a local generating company, which makes use of the lakes on the side of Snowdon mountains, and whose current is largely used at the Welsh slate quarries. Eventually the Corporation will have a supply of power of its own, drawn from Lake Eigiau, in the same district.

None of the aluminum producers publish statistics of production, and any figures appearing in print are only guesses. For instance, the 'Mineral Industry' gives 2000 tons as the yearly output of the British Aluminum Co., and the London *Times* says 1500 tons. The yearly reports of the British Aluminum Co. do not give much detail. The gross profit for 1907 was £149,783, and the net profit £120,481. Out of this, £28,514 goes to debenture interest, £43,034 is payable on various preference and ordinary shares, £20,000 written off for depreciation, £8986 is used in redeeming some funding certificates, and £17,991 used in cancelling certain debentures. The profit for this year was rather less than in 1906, when the gross profit was £178,900.

In my letter published April 25 I mentioned that the Clitters United Mines, Cornwall, had passed out of the control of the Schiffs into that of the Allen-Meyerstein group, owing to financial difficulties which the latter undertook to remedy. Since then the expectations of relief have been found to be premature, and the expected funds have not been forthcoming. The debenture holders, in order to protect themselves, have forced a receivership upon the company. A scheme is now being formulated for reconstruction, whereby the present 118,826 shares of £1 each will be exchanged for a similar number of 10s. shares credited with 5s. paid in. Creditors of the company are to be offered shares in full satisfaction of their claims, and debenture holders will receive similar debentures in the new company. This failure of the Allen-Meyerstein group to find the money is regrettable, for it casts a shadow on some of the other commitments of the group. For instance, the South Crofty is to have its mills doubled, and before long Botallack will be wanting more money.

Another unfortunate incident in connection with Cornish mining is the closing down of Tywarnhaile. This is an



old copper mine between Camborne and St. Agnes, not far from the north coast of Cornwall, and it is notable among other things as having been the scene of early operations in connection with the Elmore oil process and the Elmore vacuum process. Three years ago the Consolidated Goldfields of South Africa, Ltd., put up some money for reopening the mine. Electric pumps, gas-power plant, and other modern appliances were provided, and the vacuum plant erected. With Professor S. H. Cox as chairman and consulting engineer of the company, and with Captain W. R. Thomas as manager, things looked hopeful enough, but last month Fischer Wilkinson, consulting engineer to the Consolidated Goldfields, rather unexpectedly advised his clients that the work should be abandoned. The mine is now being closed down, and the funds in hand, some £9000, will probably be distributed to the shareholders. Naturally Prof. Cox, Mr. Thomas, and Cornishmen generally, are in disagreement with Mr. Wilkinson. The difference of opinion centred chiefly around the method of mining, Mr. Wilkinson having no sympathy with the methods of mining commonly pursued in Cornwall. He argues that, with the altered conditions in Cornwall, operations should be conducted on a larger scale, and on modern lines. This is, of course, a matter of opinion, but my view is that if operations should be conducted on a larger scale, the operations should have been undertaken at Tywarnhaile, instead of closing the mine down. Pumping has only been effected to the 40-fathom level, and no ore of importance has been found. This was far too shallow work. It is not to be supposed that the old owners of the mine had left any valuable ore so near the surface. To have been of any value the pumping should have been completed to the bottom, and exploration work should have been started where the old miners left off. However, it is too late for

me to say anything now about Tywarnhaile, and instead I will recommend that the Consolidated Goldfields transfer the plant to Wheal Busy or Killifreth, two mines near Chacewater that would be well worth re-opening on a large scale.

Recent developments at the Great Boulder Proprietary go far toward proving that Hermann Landau's lament over the impoverishment of the Kalgoorlie deposits at depth has little basis of fact. Richard Hamilton, manager of the Proprietary, reports that at the 2200-ft. level driving has been done to the extent of 350 ft., and that the ore is unusually rich. Across 300 ft. the ore averages 29 dwt., and for 50 ft. it yields 5 oz. The vein is about 5 ft. wide, but at some places is as much as 12 ft. The ore now being developed at this level is not reckoned in the ore reserves, which are figured at 650,870 tons, down to the 2000-ft. level, with an average content of 17¼ dwt. The ore varies in value from 9 to 45 dwt., and Mr. Hamilton exercises a judicious selection to ensure economical treatment. During 1907 the total ore treated was 152,118 tons, and the extraction was valued at £564,274. The profit was £341,976, out of which £28,043 was paid as taxes, £45,000 placed to the depreciation fund, and £262,500 paid as dividend. The yield of gold during the last four years has been practically invariable in amount. The ore is a sulpho-telluride. It is dry-crushed and roasted, after which approximately two-fifths of the gold is extracted by amalgamation and three-fifths by cyanide. The plant has just been extended so that the amount of ore treated will shortly be increased to 15,000 tons.

KALGOORLIE, WESTERN AUSTRALIA.

Chamber of Mines Report.—Labor Costs. — Water Supply. — Great Boulder. — March Output.

The annual report of the Chamber of Mines is generally of much interest, as one is able to gauge from it how that body views the mining industry. The speech of the chairman, Mr. Hamilton of the Great Boulder, has caused much comment. Among other things his report says: "The present trend of legislation in both State and Commonwealth Parliaments is to make the lot of the employer of labor increasingly difficult, and much more work and responsibility will in future be cast on the Chamber and kindred associations formed for the protection of the employers' interests. The shrinkage in the gold output, and the drop in the value of the ore treated, have been prominent features in West Australian mining for the past four or five years. Since 1904 the value of the yield has decreased on an average by $1,626,375 per annum. The tonnage treated has gradually increased from 2,160,657 in 1903 to 3,007,043 in 1907. Mining in West Australia is getting down to a low-grade basis, and reminds us that unless working costs can be still further reduced we cannot hope to maintain employment for the number of men now working here, since many of the mines are reaching a point where there is little or no margin of profit. I am constrained, therefore, to sound a warning note against agitations for increased wages, which some of the unions are discussing at the present. When the working costs approximate closely to those in the more favored mining districts in the Eastern States, millions of tons of low-grade ore in this State can and will be profitably mined and treated; but may we hope to realize such a desideratum? Much has been done in this direction by mechanical and metallurgical improvements; further advance will be made in these matters; more might be done in bringing down the cost of transport, and in turn, of foodstuffs and general supplies, to enable a reduction in wages, and in salaries. This must be faced sooner or later; there is no inducement for the investment of capital in mining enterprises under such conditions as obtain. The average grade of ore throughout the State will not exceed $12. Recent developments in some of the Kalgoorlie mines indicate that the orebodies will live down to great depths, and assay values met with in the lower levels are more uniform than were those of the upper levels. The outlook for mining could be regarded as hopeful if more reasonable industrial conditions were possible of attainment. Much has been done in efforts to suppress gold-stealing, but the evil is hard to cure."

The last issue of the Chamber of Mines monthly publication contains a most interesting article on 'The Mines and the Water Supply,' showing to what extent the water scheme has benefited the Kalgoorlie field. Following are a few extracts: "As a factor in the great desideratum of the reduction in working costs, the Goldfields water supply has played no inconsiderable part. The mines and companies constituting the Mines Water Trust get water at $1.20 per 1000 gal., while previously their water cost $1.20 to $1.44 per 100 gal. It is estimated that on the whole the actual cash savings to the mines in the Water Trust during the four years that the agreement has been in existence has amounted to over $1,750,000. The benefits conferred by the water supply on the mining industry are admittedly very great, but it is quite certain, and ought to be as readily admitted, that the State in benefiting the mining industry has also reaped enormous benefits itself. We may safely say that were it not for the water supply, mining operations on the Kalgoorlie fields would now be conducted on a very much smaller scale than they are."

During the month there have been no startling developments in the mines. The last progress-reports of the Great Boulder and the Ivanhoe show satisfactory results in all parts. The Boulder Deep Levels, which gained no little notoriety a few years back on account of a swindle worked, had an encouraging strike at the 1100-ft. level, where 13 ft. of ore was cut worth $16.70 per ton, with another 9 ft. of lower grade. This mine is situated in a group at the extreme south end of the 'Golden Mile.' It is to be hoped that something of a permanent nature will be opened up in this direction. Having filled up practically all its area, the Kalgurli Co. is about to stop dumping its residue in the old style, and is preparing to pump the slime away as it comes from the filter-presses. The Cassel plant has been started on the Lake View Consols for the treatment of its huge residue dump. When this plant is in working order, a full description will be given in my regular correspondence. The following table presents a review of the economic results obtained in this district for the month of March:

Name of mine.	Tonnage.	Value of output.	Profit.	Dividend.
Associated	10,395	$108,000	$ 33,000	$
Associated Northern..	3,730	47,000	26,000	
Golden Horseshoe ...	23,484	250,000	100,000	
Great Boulder	13,848	230,000	125,000	
Great Fingall	22,023	175,000	65,000	155,000
Hainault	6,210	37,000	2,600	
Ivanhoe	19,645	210,000	105,000	450,000
Kalgurli	10,775	145,000	80,000	225,000
Kalgurli South	9,029	61,000	9,000	
Lake View Consols..	9,868	59,500	6,500	
Lancefield	6,692	47,000	*13,000	
Oroya-Brownhill	12,024	80,000	20,000

Sons of Gwalia	13,130	105,000	35,000	80,000

*Loss.

TORONTO, CANADA.

Elk Lake City. — Discoveries at Silver Centre. — New Plant at Cobalt. — Ore Shipments.

A great deal of machinery is being installed by the producing mines of the Cobalt camp. The Kerr Lake company has put in a Rand-Jenckes hoisting engine with a capacity of 3000 lb. The Nova Scotia has installed a Rand-Jenckes hoist. The Nipissing has ordered two hoisting engines with a capacity of 3500 lb. each. The Little Nipissing has put in a large hoist and an 8 by 12 winding-engine. The Silver Queen has installed a 12-drill Rand compressor and is putting in a 100-hp. boiler, which will be one of the most complete plants in the camp. The Coniagas is putting in a gas-

producer plant to furnish power for the concentrator. Shipments are steadily increasing. Last week, ending May 16, was a record one, with shipments from a dozen mines reaching a total of 447 tons. The following is the official record since January 1, stated in pounds:

	Week ending May 16.	Since January.
Buffalo	.....	563,810
Coniagas	.....	380,910
Cobalt Lake	65,845	246,455
Crown Reserve	.....	40,000
Cobalt Central	49,200	156,380
City of Cobalt	.....	338,600
Drummond	.....	92,340
Foster	.....	238,400
Kerr Lake	61,960	392,670
King Edward	.....	127,240
Larose	89,000	1,981,652
McKinley	60,000	1,243,900
Nipissing	133,020	1,316,920
Nova Scotia	106,765	227,565
Nancy Helen	.....	140,420
O'Brien	63,800	1,826,870
Right of Way	60,500	181,180
Provincial	.....	143,210
Standard	.....	39,730
Silver Queen	.....	524,200
Silver Cliff	.....	52,000
Silver Leaf	.....	132,800
Townsite	.....	85,100
Temiskaming & H. B.	60,000	599,000
Temiskaming	88,140	325,390
Tretheway	.....	679,916
Watts	66,000	180,430
Totals	895,230	12,304,448

Great activity is being manifested in connection with Cobalt camp and its extensions to the northwest and south, which, in the opinion of many, promises, on the completion

O'Brien Shaft, Cobalt.

of transportation facilities, to rival the original field of operations in the matter of shipments. The attention of prospectors of late has been largely directed toward Elk lake, on the Montreal river, and the new camp of Silver lake, situated in Mickle township, about 1½ miles west of James township. With the opening of navigation many prospectors and mining men have gone to these camps, and development work has been actively begun on a large number of claims. There are said to be in the Elk Lake district some 165 claims having good native silver showings. The Moose Horn mine, in James township, about a mile east of Elk Lake city, is the first property in the new district to be equipped with machinery. This mine has 10 tons of ore ready for shipment. The property embraces four 40-acre claims, all of which have passed inspection. A remarkable discovery was recently made at Elk Lake city in the course of excavation for a cellar at the Grand View hotel. At a depth of about 3 ft. a vein was struck, from which a nugget of silver weighing about 400 lb. was taken.

The formation and mineral indications of this district differ considerably from those of Cobalt. There are miles of diabase and conglomerate rock bearing well defined veins often running very close together, the presence of silver being generally indicated by a capping of specular iron. When this occurs, calcite and smaltite are usually found at a depth of a few feet, and a short distance farther down native silver is frequently discovered in good quantities. The known mineralized area of the Silver Lake district is rapidly extending. One of the most noted locations is that of Sam. Otisse, on the west side of the lake, where a dozen veins were discovered last fall on the outcrop, one of them being nearly solid silver and about 4 in. wide. Hubert and Bloom lakes, lying to the north and west of Silver lake respectively, also offer tempting opportunities for the prospector, and a large number of claims have been passed by the inspector on native-silver showings.

At Silver Centre, the name by which the new camp to the south of Lorraine township is now known, several new discoveries are reported, and many properties have changed hands. On the Mayhew property, adjoining that of the Haileybury Silver Mining Co., a 10-in. surface-vein of smaltite, niccolite, and native silver was discovered. The Haileybury Co. is steadily continuing development, and is sacking large quantities of ore. An assay office and a general store have been opened on Lake Temiskaming, and a post-office will shortly be established.

Dr. Robert Bell, assistant director of the Canadian Geological Survey and a member of the staff for over 40 years, has received notice of his superannuation, to take effect June 1. He will receive a superannuation allowance of $1950 per year during life.

CANANEA, MEXICO.

Greene-Cananea.—Work of Reconstruction.—Trial Run of Furnaces.—Mine Development.—Fundicion Smelter.

The Greene-Cananea Co. has at present about 1100 men on its pay-roll. The greater part of these men are employed at and around the smelter. Although the heavier part of the work of re-construction is completed, there is still much to be done, and it will be at least July before the plant is completed and ready for operating. C. A. Shelby, the superintendent of the smelter, expects to start up two furnaces within a month to try the new system. It is not expected, however, that these furnaces will be run continuously, but merely to thoroughly test the new system of handling the ore from the mixing-beds and feeding it directly into the furnaces from the steel bins. This will probably not mean a general re-opening of the camp. One of Mr. Shelby's objections to this trial is that it may be mistaken by the public for an official resumption of operations, which would bring a large number of men into camp looking for employment, while the fact is that already a sufficient force is employed to carry on any experiments that may be undertaken.

The eight new furnaces have been completed for some time. Work is still being done on the steel bins above the smelters, on the installation of the belt-conveyor which is to carry the ore from the mixing-beds to the bins, on the slag-haulage tracks, and on the addition to the power-house for a large condensing plant, together with considerable finishing up of work all around the plant. A good deal of railroad work has been done since the shut-down, which includes the completion of the track to the Duluth mine, double tracking above the concentrators to the Veta ore-bins, and considerable trestle and bridge-work. At the mines various improvements have been made in the older properties, the only active development being at the Duluth, which work continually meets with marked success. One of the head mine officials stated that there is enough ore proved up above the 200-ft. level in this mine to last for three years of production, with heavy extraction. The camp is in much better shape than is generally supposed. Practically all of the business houses are open. Real estate values were expected to drop very low after the shut-down, while in reality houses and lots can be purchased but very little cheaper than formerly.

The blowing-in of the new Douglas Copper Co.'s smelter at Fundicion, Sonora, May 17, marked an epoch in the development of the mining industry on the west coast of Mexico. Heretofore every pound of ore shipped from the Pacific slope had to bear the heavy expense of transportation to distant markets, first by pack or wagon-train from points difficult of access to the nearest deep-water port or to the railroad. If shipped from a port the ore either went around the peninsula of Lower California and north to San Francisco or Seattle, or it made the trip south around the Horn to Europe or New York. If shipped by rail, freight and the custom-house expenses, together with the inevitable shrinkage in the ore from losses on its hard ride and transfers on the way to inland smelters, meant tremendous charges and reduction of net profit. The new smelter affords to an extensive territory a near-by market for the output of its mines. The plant is located on the main line of the Cananea, Rio Yaqui & Pacific Ry., south from Guaymas, about midway between the Yaqui and Mayo rivers. This railroad, together with the Sonora railway, runs through a mineral country from Nogales, at the international boundary line, down into Sinaloa, with Guadalajara as its ultimate terminal. Feeders greatly increase the tributary zone. At Torres, on the Sonora railway, the branch line to Represo brings in the products from La Colorada and Minas Prietas as well as from the region to the east, even beyond the Yaqui river. Just north of Fundicion the rich Yaqui mining country is being penetrated by a branch line running up the river, and to the south the Alamos branch opens up that well known district. About 100 miles farther south the Kansas City, Mexico & Orient Ry. is crossed by the main line, that road affording an outlet from the rich Fuerte and Choix mining country. Ore originating on the Gulf of California or the mainland coast farther south finds a near-by port at Guaymas, on the Sonora railway, or at Topolobampo on the Orient railway, from either of which ports it can reach Fundicion by rail. The plant was contemplated originally only for smelting ores from the Douglas Copper Co.'s near-by mines, chief of which is the El Cobre, in which mine alone sufficient ore is blocked out to feed the smelter for five years at its present capacity.

As yet but the first unit of the plant has been built, of which the more important installations are as follows: Morrison suspension fire-box boilers of 250 hp. each, designed for work at 150-lb. pressure; tandem compound Bates blowing-engines, direct-connected to Root high-pressure blowers; Bates vertical cross-compound engines, direct-connected to Western Electric Co. generators supplying current for driving all machinery and pumps, for which direct current at 500 volts will be used, while lighting will be at 110 volts; a 44 by 160 in. Power & Mining Machinery Co. furnace with 15-ft. settlers; 11-ft. balloon-shaped dust-chamber connected at one end by 6-ft. down-takes with the furnaces and at the other end with a self-supporting steel stack 12-ft. diam. at the base and 8 ft. at top, with a total height of 177 ft.; Jeffrey steel-pan roller-bearing conveyors, which elevate the weighed charge to the feed-floor, discharging it into a steel bin at each side of the furnace.

A 36-in. gauge steam railway reaches all parts of the plant. The ore as received is unloaded directly from the railroad cars into the narrow-gauge cars standing alongside, the sample going to the sampling mill while the balance is hauled over an elevated track and dumped into bins. From these bins the ore is drawn off below into charge cars, when wanted for smelting, and dumped into the Jeffrey furnace conveyors mentioned above. Automatic sampling and a general elimination of hand labor throughout in the movement of material, electric transmission of power, and the employment of the latest improved designs everywhere, indicate the thoroughly modern character of the plant.

The negotiations for cessation of hostilities with the Yaquis which took place recently affected only a portion of the Indians engaged in the conflict. This guerilla warfare might have been terminated a long time ago but for collusion on the part of those who found in it continuous opportunity for graft. The story of this Sonora outrage would equal that of San Francisco's corruption.

BUTTE, MONTANA.

Butte & Superior.—Anaconda Smoke Suit.—Anaconda Copper Co.—East Butte.—Butte & Buxton.

The Butte & Superior election was almost entirely by proxies. F. Augustus Heinze, N. Willis Bumstead, George Wesley Davis, J. A. Coram, George H. Flint, Charles R. Leonard, C. F. W. Dillaway, M. Sellars Largey, C. D. Coram, E. L. White, S. S. Rosenstamm, John MacGinnis, and Henry Mueller were re-elected. The new directors are George H. Flint, H. M. Burton, and George Baglin. The election was the only matter that came before the meeting, and there was little opposition to the men put on the board, though a minority of stockholders had been organized in New York to protest against the management. This opposition is seeking to form a committee of stockholders to make a thorough investigation of the condition of the company's affairs. They are not satisfied with the close relations existing beween the vendors of the property and F. Augustus Heinze, and there is much complaint over the fact that it was represented to them that there was $2,000,000 cash in the treasury when only a small fraction of that sum was ever provided, while the vendors apparently met their contract with the company by depositing in the treasury 95,000 shares of stock at $15 per share, when it was selling on the market at $5 per share, and is now selling at $3. It also develops that all the contracts for the purchase of the property have not been met, and that there is still due the Daly estate $75,000. This was due last January, but an extension for six months was obtained. At a recent meeting of the directors in Boston, President J. A. Coram and F. A. Heinze, the latter being chairman of the executive committee, made statements that the company would soon be shipping 500 tons of ore daily, and that within three months the company would be on a self-supporting basis. In Butte that was known to be impossible, and if the company is in position to ship 500 tons per day a year hence it will be doing better than is expected of it.

W. B. Lowe, a geologist and mining engineer, who recently made an examination of the North Butte Extension property, has made a favorable report. He traced five veins and several strong spurs onto the property. Any one of four of these veins is, he says, sufficient to make a mine that will compare favorably with any in the district, and that copper will be produced at a less depth than that at which pay ore is reached in the average mine in Butte. Two lines of railroad are easily accessible from two points on the property. Geographically the claims are advantageously located. The Butte & Superior Co. has cross-cut the Blackrock vein at a depth of 1000 ft. The vein is about 60 ft. wide and carries much ore, mostly zinc, which can not be treated in this part of the country. There is talk of mining the ore and shipping it to Kansas City to be treated for zinc and silver. It is claimed that the ore will return net about $22 per ton. The vein will be explored at that depth and sinking will also be continued until the shaft reaches 1200 ft. It is now 1080 ft. deep. So many 'strikes' have been reported by the Butte & Superior that there is always some suspicion attached to news from that quarter, but assays show 41% zinc in the ore on the 1000-ft. level, a small percentage of copper and about 25 oz. silver to the ton. The Butte & Superior authorized the issuance of $500,000 in first mortgage bonds in order to raise money with which to carry on development work and to pay for the property. The bonds can not have found a ready market, for the final payments on parts of the property have several times been extended, and will fall due again next month. The Raven Mining Co. has cut the Raven vein from the 1000-ft. station of the incline shaft. The vein is 26 ft. wide, the ore assaying 2% copper, with some silver and gold.

The final arguments in the Federal Court on the smoke injunction case, in which the Deer Lodge valley farmers are suing to close the big Washoe smelter of the Amalgamated Copper Co. at Anaconda, will begin May 26, before Judge Hunt in Helena. Each side will argue 10 days, and the findings of the Master in Chancery will then be taken

under advisement by the Court. A decision may be expected some time in the fall.

The annual report of the Anaconda Copper Mining Co. for the year ending December 31, 1907, contains some interesting information relative to the operations during the year. President John D. Ryan says that because of the high price of copper early in the year it was deemed advisable to treat ores of a lower grade than had been extracted in any previous period in the company's history. Much of the product from the treatment of the low-grade ores was not marketed until late in the year, some product of ores mined as early as March not being sold until the latter part of the year, at prices 10c. to 12c. per lb. lower than were ruling at the time when the ore was extracted. The copper on hand at the end of the year was produced during the period of curtailment, and cost the company $163,105 more than was realized from its sale. During that period the output of the company was as low as 35% of the normal, and finally production was stopped completely, at the beginning of December. The mines were re-opened March 1, and by the latter part of that month the production had about reached the normal. By the first of May the production-figures showed a considerably higher grade of ore and lower cost per pound of copper than have been realized at any time in years. The veins in the Anaconda mine had been opened on the 2200 and 2400-ft. levels; on the 2000 of the St. Lawrence and 2200 of the Neversweat, but practically no stoping was done on them until mining was resumed in March. A new vein yielding a good concentrating grade of ore has been found in the upper levels of the St. Lawrence, and has been opened a distance of 500 ft. in length. The south vein of the Anaconda group has also been opened on three levels, and half of it is smelting ore. The Washoe smelter treated for all companies last year 2,582,611 dry tons of ore and other copper-bearing material, including 1,110,203 tons of ore from the mines, 2966 tons of concentrate, 16,250 tons of slime, and 24,226 tons of slag from the old smelter. There was produced 63,055,661 lb. fine copper, 2,001,350 oz. silver, and 8290 oz. gold. The gross earnings of the company were $18,751,133, and the profit was $3,378,220. The surplus at the end of the year was $9,183,241. The value of the copper, silver, and gold on hand, taking account of the loss on copper, was $6,002,643.

That the Amalgamated Copper Co. has no thought of curtailing production, but on the contrary is gradually increasing its output of copper, is evidenced by the fact that two more mines have been added to the list of producers, work having been resumed on the Neversweat of the Anaconda Co. and the Gray Rock of the Butte & Boston Co. The Neversweat was closed at the time of the general shut-down of mines in the Butte district last fall, and operations were not resumed at the time of the general resumption in March because the shaft of the mine was being re-timbered and repairs were being made to the hoist. The Neversweat employs about 200 men and its output is about 300 tons of ore per day. The Neversweat is a rich mine and is on the same veins as those on which the Anaconda mine is working.

Work is being done preliminary to a resumption of operations by the East Butte Copper Mining Co., which owns a number of small mines and some immensely rich ground just south of the Pennsylvania mine, the richest of the Boston & Montana properties. The East Butte has 12 shafts on its ground, all but two of them having been used by lessees. The two main shafts, No. 1 and 11, are situated at the extreme north and south ends of the company's ground, and are being connected by cross-cuts. Shaft No. 1 is 900 ft. deep and is probably the best-built three-compartment shaft in the Butte district. No. 11 is nearly 500 ft. deep. There are some 20 known veins in the East Butte ground, striking east and west, the largest of which is about 80 ft. wide. A body of copper glance was cut in the shaft near the 900-ft. level at the time work was stopped last fall, when the Washoe smelter and the Amalgamated mines closed on account of the unsatisfactory condition of the copper market. Frank M. Sullivan, Patrick Wall, Henry Mueller, William A. Paine, and other stockholders of the company have personally advanced funds necessary to carry on and complete the development planned last year for bringing the mines to a producing and dividend-paying stage. The plans include sinking the two main shafts to a depth of 1500 ft. and cross-cutting every 200 ft. William Clancy, the company's mining engineer, made measurements of the ore in sight last fall above the 400-ft. level, and placed the amount at 1,000,000 tons.

The Butte & Buxton Copper Mining Co. has been incorporated for the purpose of developing the Lackner properties in the Summit Mountain district, 10 miles southwest of Butte and two miles from Buxton station, on the Oregon Short Line. Recent developments show an orebody 10 ft. wide, the lead itself being from 60 to 100 ft. wide. Five feet of the ore is claimed to assay 4 to 8% copper, 10 to 20 oz. silver to the ton, 10 to 20% lead, with about 40c. in gold to the ton.

SALT LAKE, UTAH.

Smelting Conditions. — Utah Smelting Co. — Boston Consolidated.

The past week has wrought a perceptible improvement in the mining and smelting situation in and around Salt Lake. Authoritative information to the effect that the United States Smelting, Refining & Mining Co. would positively resume the purchase of custom lead ores by the middle of June has been received with much satisfaction by ore producers; while the opening of the ore-purchasing department of the Tintic Smelting Co. for business has been hailed with equal gratification; thus bringing a return of old-time competition in the local market for lead ores. At this time the Garfield smelter of the American Smelting & Refining Co. is the only place where copper ores can be sent for treatment within the State of Utah; but this company has all it can do to take care of the contracts it already has on hand. In fact, it has not had furnace capacity to treat all the ore received, and the result is congestion to the extent that the smelter management has experienced much inconvenience of late. The bins at the smelter are filled, while many thousands of tons of ore have been unloadded from the cars in which it was brought from the mines and piled up in the yards, awaiting disposition later. Three blast-furnaces are in commission and the fourth is to be started up before the end of the month. Definite decision has been reached to place the smelter of the Utah Smelting Co., near Ogden, and which has been leased to a local syndicate, in commission again. It is said that sufficient contracts have been obtained to warrant doubling the present furnace capacity, and in all probability the plan to add converters will soon be carried out. No steps have been taken as yet toward making application to the Federal Court for a resumption of the copper smelter of the United States company, nor will any such move be made at once. However, the management is considering the erection of a sulphuric acid plant.

The American Smelting & Refining Co.'s lead smelter at Murray is running on low tonnage, only three furnaces being in service, and the monthly payroll is reduced to $20,000. The American has no contracts with the large lead producers of Utah; some ore is coming from Park City, a few small Tintic mines are contributing, but other than that the Murray plant is getting very little ore from Utah camps.

It is expected that the third blast-furnace at the Yampa smelter, in Bingham, will be ready for commission within ten days, and work is progressing satisfactorily with the installation of the converter department, which is being done at an expense to the company of about $80,000. The Yampa smelter is now treating an average of 800 tons of ore per day, but it will have equipment to treat 1000 tons per day by July 1.

The fourth unit of the concentrating mill of the Boston Consolidated Mining Co., at Garfield, is in operation. Each unit is intended to treat 200 tons of ore per day. The company is shipping 300 tons daily from the sulphide end of the mine, direct to the smelter.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Paint will adhere to zinc if the latter be first coated with the following wash: Dissolve 1 part each of nitrate of copper and sal ammoniac in 64 parts of water to which add 1 part of commercial hydrochloric acid. Such a wash requires 12 to 24 hours to dry.

Silication is the union of silica (SiO_2) with a base to form silicates. This action must not be confounded with silicification, which involves the addition of silica to a rock without union with bases. Silicification, however, may take place by complete substitution of quartz in the room of another mineral which passes away in solution. This process results in making a pseudomorph.

In marking mining locations on the ground, a substantial compliance with the State law is all that is required, with reference to the character of posts. We do not think that the Courts would deprive a bona fide locator of his claim simply because his posts, which should be 4 inches square, are only 2¾ inches. They would hardly uphold a hostile re-location of the claim made on the sole ground that the posts of the original location were too small by one and one-fourth inches.

A mill-site may be acquired disconnected from the ownership of a mining claim. If a mill is erected on the mill-site, the unpatented title vests, and cannot be defeated by re-location simply because mining claims from which ores were reduced in the mill are subsequently abandoned. Even if the mill-site is an adjunct of a located lode-claim, if a mill is erected thereon we do not think that upon the abandonment of the lode-claim a re-locator could re-locate the mill-site and take the mill.

Lime is added to cement mortar for economy, and physical tests show that in quantities less than 15% the cost of the mortar is reduced more rapidly than the indicated strength, and is therefore economical. But addition of lime is equivalent to over-liming in the manufacture of cement, developing the fatal defect of gradual disintegration. This would seem to be due to the carbonation of the lime, causing expansion, which breaks up the imbrication of the crystals, which is what constitutes the 'set' on which the strength of the cement depends.

Ore deposits formed by aqueous agencies constitute certainly 99% of all those the origin of which has been demonstrated. Of these, according to Charles R. Van Hise, more than 95% are due to meteoric waters, but in the last few years there has been a growing tendency among geologists to attribute a larger number of ore deposits to the action of magmatic waters. These are waters originally present in the deep-seated voleanic rocks, which are forced out when solidifieation of the fused mass occurs. This solidifieation may be likened to the setting of cement.

Metallic tantalum, which has lately been widely used for filaments of incandescent electric lamps, has been known for a century, but isolated in pure form only as recently as 1903, when Moissan reduced it in the electric furnace. The most commonly occurring tantalum minerals are tantalite and columbite, which consist of tantalates and niobates of iron and manganese in varying proportions. In the United States these minerals are most abundant in the Black Hills, South Dakota, and also occur in small quantities in Connecticut and North Carolina. Tantalite is rich in the metal and contains about 84% of tantalum pentoxide, while columbite contains but little tantalum and is mainly composed of the practically worthless and often detrimental niobic pentoxide. The minerals are marketed on the basis of the content of tantalic acid (Ta_2O_5). The limited market is now overstocked, and it would probably be difficult to dispose of any of these minerals at present.

For assessment work on mining claims, structures placed upon the claim in good faith for the obvious purpose of developing the mine are considered improvements within the meaning of the law. Hoisting-works would be so regarded, but a boarding-house for miners would not be considered a fixture. This is based upon judicial decisions and common sense, and the rule obtains in all the mining States and Territories. In Montana the Courts had to deal with a peripatetic house which did service on one claim as improvements for patent purposes, and was thereafter moved and similarly used on a number of other claims in the district. Portable engines have been overworked in the same way. A gasoline engine and a hoist might be considered improvements on a claim, if erected and operated for the purpose of mine development. It depends to a large degree upon the question of good faith.

Silver sulphides in the upper oxidizing zone are rapidly converted into sulphate, which is readily soluble. In this form it would be leached downward until it should mingle with a solution of ferrous sulphate, when the silver might be re-precipitated as sulphide, as shown by the reaction,

$$Ag_2SO_4+12FeSO_4+12H_2O=Ag_2S+4Fe_3O_4+12H_2SO_4$$

or a reduction to native silver might occur under the same circumstances, as follows:

$$Ag_2SO_4+3FeSO_4+4H_2O=2Ag+Fe_3O_4+4H_2SO_4.$$

Organic matter, which is always present in the waters near the surface, will likewise reduce the silver to the metallic state, but the presence of chlorides such as those of sodium and magnesium, which are never entirely absent, and in some desert regions particularly abundant, will effect precipitation of the silver chloride appearing as horn silver. It is evident that silver, being so readily precipitable from solution by reagents which are sure to be available near the surface, cannot travel to such depths as copper, and hence we observe a tendency to relatively superficial secondary enrichments in silver veins, while if copper had been present the secondary ores of that metal will be found more abundantly at a lower level below the silver.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Mining Law.

The Editor:

Sir—It is pleasurable to observe that Mr. Charles H. Shamel insists upon further discussion of the 'apex question' and the extra-lateral right conceded by United States statute to the locators of quartz-mining claims. It is frank confession that he recognizes reserve ammunition still in the possession of the besieging forces. I may acknowledge that I entered the lists on the invitation of the editor of *Economic Geology* not as a radical, insistent upon sweeping away the old law, but as an apologist for the Congress, which had been cudgeled unceremoniously by Mr. Purington. My main point was to ascertain why our body of legislators should have framed a mining statute so little consistent with geologic conditions, and the reason was found to lie in simple unconsciousness of the truth, or of the existence of any means for reaching the truth, about the characteristics of ore deposits. The statutes of 1866 and of 1872 were drawn, debated, and enacted into law, without consultation with or advice from a single educated experienced geologist, and the arguments in favor of the law were bolstered up by reference to miners' rules in California and Nevada, and by letters from uninformed mine operators in other western States and Territories. The gentlemen from Nevada, California, and Oregon distinctly 'had the floor' in that debate, and the only obstinate party who 'wanted to be shown' was not from Missouri, but from Ohio. Senator Sherman was sincere in his effort to provide a wise statute, having come to the conviction, in divergence from all precedent in the land of common-law origin, that mineral veins on Government land should be granted in fee-simple, and if anyone had hinted that there really was anybody who knew more about veins than Senator Stewart, that person certainly would have been consulted by the Senator from the 'Buckeye State.' It was a singular case, as if the Congress should alter the tariff on steel upon representations of the state of industry made by laborers in the works, instead of taking evidence from the consulting metallurgists, and especially from the officers of the corporation—an error which is unthinkable as regards any politician, past or present. But California and its gold had hypnotized the world, and the treasures of the Comstock had dazzled it, until the mention of a mine transported the thoughts far away to regions of romance. There is no doubt about all this. Let anyone read the congressional debates, and note the awestruck deference of the other members when the spokesman for the western miners rises to explain and demand *amparo*. Congress simply forgot all about the iron mines of New Jersey, of Pennsylvania, and New York, the copper mines of Michigan, the lead mines of Illinois and Missouri, and the fruitful lessons that might have been deduced from them. It forgot how many centuries ago Agricola had written wiser and sounder facts concerning ore deposits than any adduced by the representatives of California and Nevada in our national assembly. It overlooked the long experience of England and France and Germany in establishing equitable bases for ownership and exploitation of minerals, whether in veins or deposits of other form. The marvel is that the blunders were not more serious than they have proved in practice. Perhaps no more striking case of departure from the spirit and essence of common-law development could be found than this instance of crystallizing into a statute some of the local regulations of a small group of men, who had accidentally adopted a principle at variance with the customs of all nations and all ages, who had experimented with it, litigated more or less about it, and had spilled a great deal of blood over it, for a trifling period of sixteen years! Common law is the ripened fruit of ancient custom, with the bitter principle mollified by the beneficent sunlight of experience. It represents the way men have found to lead away from disputes, not into a bristling wilderness of contention.

Mr. Shamel must excuse my invasion of his territory of the law, since he chose to invade that of the geologist. We can both stand more firmly on our own proper ground, no doubt. The geological difficulties in the case have of course been accommodated by the concurrent growth of case-law, the dear delight of the attorney and the despair of the layman! The result is decisions by the thousands, lying as adverse and confused as the sticks in a crow's nest. Decisions can be cited pro and con to sustain any interpretation of the statute, but except where a Supreme Court decision has been handed down no honest lawyer can say to his client the 'law' is thus and so. The 'law' in California will be unlike the law in Colorado, according as the Supreme Courts of the respective States may have decided on the State laws based upon the Federal statute, unless the point has been reviewed by the United States Supreme Court. But no man need ask his attorney what belongs to him when he holds title to land whose limits are within planes extending vertically downward around the sides. The old miners in California had a feeling that an original discoverer of a vein was entitled to exceptional reward. Governments everywhere concede the same in protecting human ingenuity in the arts, but it is noticeable that the patentee's rights do not extend to all the dips, spurs, and angles that may subtend from the original happy thought, from the mere apex of invention. He has no exclusive right to a new principle wherever it may lead. He can not obtain patent to the principle itself, but only to some specific application, to some defined method for the beneficiation of the principle. He has no extra-lateral rights. If there were any justification for making broad concessions of right to discoverers it would seem to be in the case of patents, protecting a man in the enjoyment of the fruit of his initiative, which is a necessary stimulant to progress and civilization. But the law tacitly affirms that a man may

not lock up the powers of nature from his fellowmen; that whether he will or no he must be something of an altruist, not an unsocial creature. But intense assertion of individualism is characteristic of frontier communities, where the dominance of a few strong spirits is more absolute than that of oil-kings and steel-magnates, and this excessive demand for all that might follow from a discovery of outcropping mineral reflects the spirit of the times, with its maddening race for wealth, that was made in the primitive fashion suggesting Homeric and Virgilian story. Those old booted and belted Argonauts originally claimed in a vague sort of way as much ground on each side of a lode as might be necessary to protect control of the vein, no matter how far its dip might carry it. Here was clearly the mingling of the mental streams of apical greed, and of ancient restraint through recognition of the bounding planes that divided one from his neighbor. Presently there came the greed that would rise as well as descend in its quest beyond its natural borders, so we find as early as 1855 in the 'quartz mining law' passed by the Angels mining district, in Calaveras county, California, an article affirming that "he or they shall have the right to all dips, spurs, or angles of every vein originating on the claim. We understand that a vein originates on or below the surface, running downward, and not from below running upward, so that no person or persons locating a claim on either side of the boundaries of another shall have a right to a vein running through his or their claim that originates as above understood on the claim first located, but no man shall have the right to follow a vein on the length of it beyond the perpendicular line of his boundary." The question of a tunnel-locator's right under the law—in forgetfulness of that old Calaveras pronunciamento—and the privilege it may confer of getting under another fellow and raising him out of his property supposedly acquired through location on an apex, is one that to this day is not decided, nor does anyone know of a certainty what extra-lateral rights may pertain to a tunnel-discovery of a vein, in either direction.

The fundamental mining law of the United States was built upon inchoate regulations obtaining in a limited area, where the type of veins encountered had been almost wholly simple in structure, as evinced by the terms of the law itself. The demand that an apex be discovered, and the conceded right to follow the vein on its dips, spurs, and angles, expresses a conception which by no possibility could embrace such ore occurrences as those which have made the fame of Rico and Leadville, of Bisbee and Keswick, a conception which can be made to apply only through that necessity for stretching language to its elastic limit, which is imposed upon the judge when the law-maker legislates without precautionary information upon the elements of the principles involved.

The problems of cross-veins, branch veins, overlapping veins, associated but discontinuous masses, irregular masses with apices instead of a single apex—these in mere catalogue raise spectres of evil when one considers the Federal prescription for making a mining title sound. The judges have been working for forty years to explain what the law meant to say, or should have said, but did not, and perhaps in time enough cases will have been adjudicated to admit of codifying the case-law so that an ordinarily intelligent student may know with some degree of certainty what his rights under a particular set of circumstances might be. Until that time may Mr. Shamel have joy of the litigation in which he will reap well-earned rewards for patient guidance of his clients, unless he choose to turn public benefactor and help to blaze out a safe trail for a new law that may save future mine-owners from trouble without infraction of any existing rights arising by virtue of the act of 1872.

San Francisco, May 25. COURTENAY DE KALB.

Valuation of Mining Shares.

The Editor:

Sir—In determining the value, from a non-speculative standpoint of mining stock, the redemption of capital is too often ignored. Investors are frequently misled by promises of seemingly high rates of interest extending over the life of the mine, which rates, viewed in the light of 'money back,' shrink away. What appears on the face a profitable investment ultimately turns out to be a loss or returns at the best a low rate of interest. In other words, unless the value of an investment is properly calculated, the yearly dividends prove to be not profits at all, but merely the redemption of the principal. Given the life of a mine and its yearly dividends, what is the present value of its shares? The investor should expect a certain annual rate of interest for his capital, varying from 6 to 15%, in addition to the return of the capital invested at the end of the life of the mine, his sinking fund in the meantime being invested at 3%. The annual rate of interest expected varies, of course, with those factors which make up the risk, factors such as locality, climate, kind of metal mined, labor conditions, transportation, and so forth. One should be satisfied with a much lower rate of interest in Oroville (California) shares, for instance, than in the shares of a mine in Korea or Borneo. In the former case, 7 to 8% and money back would be not unreasonable, whereas 15 to even 20% should be demanded from the latter. I wish especially to insist that the rate of amortization should be assumed at 3%—the safe bank rate. Sometimes in England the rate of amortization is assumed equal to the interest received; that is, apparently the sinking fund is supposed to be reinvested in the shares in question. This appears to me unsafe. A well known mining handbook published in London gives a list of factors for determining the value of mining stock. These factors are misleading, as they assume that the capital is amortized at the same rate as the interest expected; that is, if one receives 10% on his investment, his sinking fund is to be invested at 10% in order to redeem his capital. This is a manifest error, and the results over-value the mine.

The total interest required in order to return a

certain rate of interest per year, and amortized at 3%, may be estimated as follows: Shares in a mine with two years' life must return to the buyer $56.26 per year for every $100 invested in order to pay 7% per annum and amortize at 3%. Of this, $49.26 must be invested at 3% to redeem capital, the remainder being 7% on capital. The present value of the shares is $88.87 for every $100 of net ore in reserve. If the mine has a 10-year life, the shares must pay 12.38% in order to obtain 7% per annum and amortize at 3%. Here 5.38% of the gross interest must be banked each year toward redemption of principal. The present value of these shares is 63.59% of total net profits. If the life of the mine be 20 years, under the same conditions, the gross interest must be 10.72%, of which 3.72% is the sinking fund. These shares are worth today only 46.635% of the total net profits. Here is an example. Assume a placer mine with a proved net profit of $50,000,000; life of mine, 20 years; capitalization, 5,000,000 shares at $5 par value, or $25,000,000. Our friend the promoter would exclaim: "Here are two bright new dollars for each old one!" or, as we have all recently read in a maze of financial and termological inexactitudes, "Gold for sale! 50 cents on the dollar!"

First. If these shares are purchased at par ($5), what rate of interest per year would they return to buyer in addition to money back, amortizing at 3%? The mine pays $2,500,000 per year, or 10% gross interest on investment. For a 20-year investment a gross interest of 9.72% (nearly 10%) will give money back (3% amortizing) and return in addition 6% only on investment. So this stock at par value will only yield 6% on investment and money back. Of the $2,500,000 per year, $1,000,000 must be invested each year at 3% for redemption of capital: the other $1,500,000 is the 6% profit on investment. Figure it another way: The factor for the present value of a mine with a 20-year life, amortization at 3%, and yearly dividends at 6%, is 51% of total profits. In this case 51% of $50,000,000 is $25,500,000, which is about the capital assumed. Hence a capitalization of $25,000,000 yields 6 per cent.

Second. What are the shares in this mine actually worth today, in order to return to the investor 10% interest and amortize at 3%, the dividend being the same as $2,500,000 per year? To return 10% and money back the mine should yield a gross interest of 13.72% per annum for 20 years. Hence the real capitalization should be $18,000,000, that is, the shares are actually worth $3.80 each. Bought at this price and investing sinking fund (in this case $7 out of every hundred of the dividend) at 3%, the shareholder will have received during the life of the mine 10% on investment and have had his money returned. It has been recently pointed out* that of the large number of Rand mines only two of them stand up under the test of a fair return for capital invested (in this case 8%) and money back.

The 'profits' of most are not profits in the above sense of the word, the dividends paid being the repayment of capital and in some cases an additional small rate of interest. To bring this fact home to the shareholder the author of the paper referred to has well suggested that redemption of all capital invested should be in the future added to the costs per ton of ore treated. If this be done it will show at a glance whether the profits be real or imaginary. It will also tend to keep down capital expenditure and to check in a measure the deferred payments of dividends.

To enter another field, apply this method to one of the dredging cost-sheets. Assume 300 acres of dredging ground to cost $300,000, and equipment of ground $150,000; operations to extend over 12 years; interest at 12% per annum; capital redeemed at 3%; one dredge treating 1,000,000 cu. yd. per year.

A cost-sheet including redemption of capital would appear thus:

	Per cu. yd.
Redemption of cost of ground	5.715c.
Redemption of cost of equipment	2.752c.
Working cost	7.000c.
Total	15,467c.

The first two figures (8.467c.) are, of course, dividends, and by their distribution annually the investment will pay 12% in addition to money back. The ground must yield 15.467c. per cubic yard to meet these conditions. If its yield be under this amount, the shares will pay less than 12% net interest. If it be over, the excess can be used as extra dividends or toward a special fund for the purchase of additional acreage or equipment.

I quite realize the limitations of the method of valuing property herein set forth. It can only be applied to those mines paying a definite profit extending over a known life. Such cases are not uncommon, but the data required are frequently difficult to obtain. The mines of the Rand afford a well known example. To many alluvial gold mining enterprises the test can also be applied. Where, however, the value of a property is wholly prospective or speculative, other methods of valuation must be employed. I also confess that I have, in a measure, been threshing over old straw.

These 'money back' calculations should be applied to all legitimate stocks, yet it is surprising to find among shareholders (whose all is invested in mining) how few of them really can and do rightly determine the true value of their holdings. If these people could be brought to view a mine as an annuity having a given life, and if they realized that their dividends are not all 'velvet,' running on forever, much worthless stock would remain unsold, and mining investments among this class would not eventually be so bitterly condemned.

Cyanidation of Ore Containing Both Coarse and Fine Gold.

The Editor:

Sir—The numerous responses from well known authorities on ore treatment to my letter published on December 7 last over the signature of 'Viator,' encourages me to seek the hospitality of your columns in order to offer a few comments upon the

divergent suggestions made, and at the same time to express my thanks for the light which has been thrown upon the subject.

The broad form of query, to which you invited replies, has elicited a good deal of support for the method of crushing in water when the ore contains a considerable proportion of amalgamable gold, with subsequent treatment of the tailing only by cyanide. As pointed out by one contributor, the importance and efficiency of our amalgamation recovery has caused this system to remain common practice in South Africa. Those who advocate crushing ores of the class referred to, in cyanide solution, recommend the following methods for recovering the coarser gold:

(a) Use of amalgamated copper plates; their gradual dissolving to be regarded as an inevitable item of maintenance. No one, however, has dealt with the question of the copper from this source deposited in the zinc-boxes and its effect upon the clean-up.

(b) Use of spitzkasten for reducing the volume of pulp, to be subsequently ground and amalgamated in pans or similar apparatus. This method, of concentration before amalgamation, is hardly likely to afford as high an amalgamation recovery as when the whole pulp is amalagamated, since a very exact and constant regulation of the spitzkasten must obtain in order to prevent amalgamable gold, which cannot dissolve in a practicable time in cyanide solution, passing into the overflow. This difficulty also affects the recommendation of all-sliming the ore, and also presumably the gold, apart from the needless expenditure the latter course would necessitate in many cases, where sliming is not needed to expose the values thoroughly.

(c) Use of riffles for recovering the coarser gold. This method seems even less efficient than (b), and the re-working of placer sites, as at Oroville, shows how liable metallic gold of appreciable size is to escape this imitation of Nature's concentration methods. As in the previous suggestion, the high specific gravity of gold is alone relied on for its separation from a relatively deep stream of pulp, as compared with the combined effect of specific gravity and chemical affinity when the pulp flows in a broad shallow stream over an amalgamated plate. In applying both methods (b) and (c) to crushed ore after cyanide treatment there may be loss of particles of gold, whose original size was sufficient to ensure their recovery, but which by partial dissolution have been sufficiently reduced to be carried over in suspension in the pulp.

(d) Use of blanketings. No doubt, in the absence of more perfect and expensive concentrators, this device has very real merit in recovering tarnished or rusty gold, such as, even though fairly coarse, is not readily amalgamable either in a water or cyanide pulp.

(e) Only one reply deals with an expected suggestion of converting the amalgamated plate into a cathode, thus obviating solution of copper and mercury, while retaining the advantages of contact between brightened amalgamated surfaces and gold particles. Molloy's hydrogen amalgamator is based on this principle, but an even earlier suggestion, before the use of the cyanide process, is contained in a series of articles on gold milling by C. H. Aaron, appearing originally in the MINING AND SCIENTIFIC PRESS, re-published later in the *Gold Fields News*, Barberton, Transvaal, in October, 1890. This author says: "I recommend that millmen who have trouble with their plates should make some experiments, each separately, as follows:

"1. Place some bars of iron on the apron, say one across the upper end, and one on each side edge, also one in the middle.

"2. Use zinc amalgam on the apron.

"3. Dissolve a little cadmium in the quicksilver for use on the apron and in the mortar.

"4. Fix a tank so as to deliver a small stream of water, containing potassium cyanide, into the mortar constantly while crushing. (This has been done in some mills with good effect.)

"Those who have occasion to work auriferous material in pans would do well to try a solution of potassium cyanide in which a little red oxide of mercury is dissolved: the effect of this solution is to coat every particle of gold with quicksilver, which greatly aids the amalgamation. Not too much of the solution must be used, as it dissolves gold; however, it is believed that the dissolved gold can be recovered by using zinc amalgam in the pan toward the end of the operation. Before adding the solution, the pulp should be made slightly alkaline by the addition of a little potash or soda. It is believed by many that zinc amalgam is very effective in catching gold, and still greater efficieney is claimed for cadmium amalgam. The presence of zinc blende in the ore has probably a favorable effect on amalgamation by tending to prevent oxidation of the plates, with which it forms a galvanic couple in the same way as does a piece of zinc."

W. A. CALDECOTT.

Johannesburg, Transvaal, March 23.

An acid-vapor rust-proof coating may be applied to metallic tools and other articles by the following method: Prepare a sheet-iron box provided with a false bottom of wire netting. Put a layer of crushed blacksmith's coal, about $\frac{1}{3}$-in. deep, onto the sheet-iron bottom of the box, put the articles to be coated (which must be entirely free from grease and rust) on the wire net. Close the box tightly and heat over a quick fire until the bottom is red hot. After the box is cool the articles will be covered with a black glossy coat, formed by the tarry constituents of the coal. By this method the tar penetrates into the pores of the metal, and will endure as a protective coating for six months.

The coinage executed at the several mints of the United States during the month of April consisted of 7,533,835 American pieces, having a value of $28,230,682. The coinage of American pieces included 1,365,378 double-eagles, 1,096,000 half-dollars, 160,000 quarter-dollars, 1,790,000 dimes, and 3,122,457 five-cent pieces.

MEXICAN NOTES.—II.

Written for the MINING AND SCIENTIFIC PRESS
By MARK R. LAMB.

The *hacienda* Loreto is shown in Fig. 6 and 12 as it appeared during its transformation from the patio to the cyanide process. The ore-bins are of cut stone, and are more than a century old. They receive the ores from the numerous mines controlled by the company. The immense size of these bins may be judged by comparing dimensions with the 40-stamp mill shown under construction in front of two of them at the extreme right of Fig. 3. Massive masonry vats to contain water are shown in this photograph. In Mexico, roofs such as are seen in the foreground of Fig. 3 are usually made without nails. Rafters and joists are tied together with thongs and the shakes are similarly secured. The extensive roofs over the large cumbersome *malacates* or whim-hoists are so built, and seem to be as strong as ever. In these pictures the amalgamation patio is being covered with slime agitation-vats, which are shown

Fig. 7. Slime Plant Under Construction.

completed in Fig. 7. Note the apparent size of the road roller to the right of the picture, and also the height of the edge of the exeavation from which the picture is taken, showing the labor required to prepare the patio. It should not be forgotten that this work was done without the aid of modern explosives.

The picture (Fig. 8) of the supported double pipe-line shows two methods of ore transportation. The pipe-line transports pulp over a mile from the mill to the leaching-plant, while the burro, the best of the native laborers, is taking ore to the mill. These transportation lines are not competing; in fact, since the railroad merger, there are practically no competing lines in Mexico. The view of the San Matias mill (Fig. 2) shows the old works in the foreground with typical lookout towers and rifle-slots. All the old mines are equipped

Fig. 9. A Copper Furnace.

with ample house-room. Cleaning and furnishing fits them for better and more comfortable homes than are the wooden structures usually found around mines. At this point it may be well to advise the young miner or metallurgist to choose his employers from among French or English companies if he desires to live comfortably. With a few notable and saving exceptions, the American companies expect their employees, from superintendent down, whether married or single, to live in a shack, and to furnish it.* They rarely sign a contract for a term of years with an employee, and the

Fig. 8. Pulp Pipe-Line.

*[Our own experience would lead us to believe that Mr. Lamb was unduly accentuating some special cases of neglect. The American companies do not encourage extravagance, but provide well for those having charge of their operations, so far as we have seen.—Editor.]

average mill man moves about twice a year. On the other hand, the English company usually investigates the man before employing him, and then knows what to expect. They do not ask for perfection, neither do they so often get stuck with rankly incompetent or intemperate men. A man in a foreign country with a contract feels more contented and willing to give his best efforts than when he is not sure what may happen from one day to the next. If the companies but realized it, this feeling is a greater incentive than double wages. This diatribe may not be in place here, but it touches a subject of much greater importance than the efficiency of

Fig. 10. An Adobe Smelter.

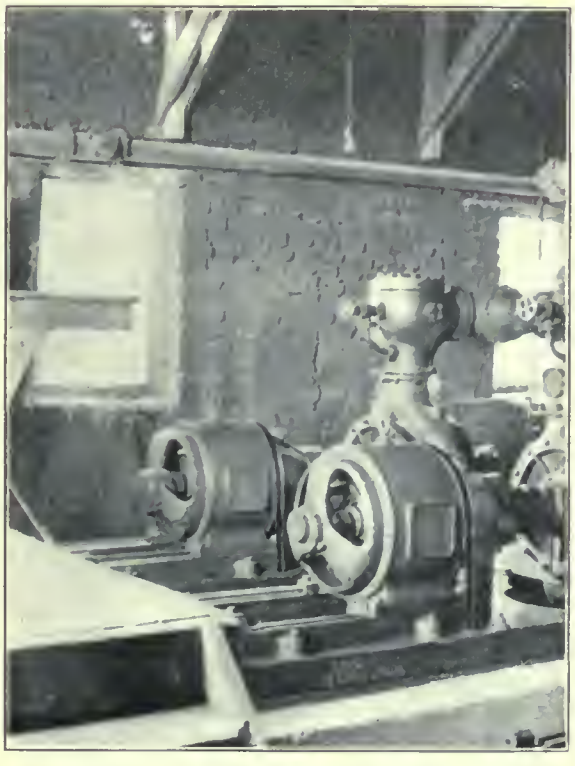

Fig. 11. Direct-Connected Centrifugal Pumps.

Fig. 12. Cyanide Plant in a Patio.

pumps or the best ore-mixture for pyritic smelting.

A two-stack copper smelter, built to smelt Cananea ores, is shown in Fig. 9. It was a commercial success, producing metallic copper directly from ore. The copper was worked into utensils and sold on the ground to consumers, thus combining under one control, mining, smelting, converting, manufacturing, and wholesale and retail selling, which is more than the present Cananea company is doing. The hat of the blowing engine for these two stacks is just visible between them. Fig. 10 depicts the ruins of a more pretentious reverberatory and roaster of adobe construction throughout. The two single-stone rollers of a Chilean mill are visible on the left. Near this is a smelter that was built for copper-matting silver ores. The fact that the ore contained no copper did not deter, as scrap copper was shipped in from the States to the nearest railway station, whence coke and copper-scrap were hauled 40 miles in two-wheeled carts. It is hardly necessary to say that the plant is not now in operation, though an approaching railway may induce the resumption of operations.

The manner of bringing water to the old plant in times past is shown in Fig. 5. Note the protection from destructively inclined persons afforded by the rifle-towers. The *noria alta* (high water-wheel) is built on a bank of the river and reaches from water-level to a point high enough to convey the water by gravity to the treatment plant. Horses traveling in a circle on the top of the well and hitched to a wooden-pin gear, operated a unique bucket-elevator which raised the water. From the top of the well it flowed along the arched aqueduct to the patio. In contrast to this is Fig. 11, showing a direct-connected high-duty centrifugal pump. This type of pump has been thoroughly tested in Mexico, and I have yet to hear anyone express preference for the mover plungers. Fifty per cent seems to be the maximum efficiency under the best conditions to be obtained in common practice. The best Swiss pumps have been replaced by triplex and quintuplex geared and belted plungers, even when the lift is not excessive.

GOLDFIELD, NEVADA.—III.

Geological Notes.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Owing to the limited extent of the underground workings and the comparative newness of the mines, the geology of Goldfield is difficult to decipher. One of the first published accounts of Goldfield appears in Bulletin No. 260 of the U. S. Geological Survey, in the form of a short report by J. E. Spurr, who visited the district in November, 1904. This was long before the big discoveries. I presume that Mr. Spurr would like to see this early document destroyed, for it was written before the necessary facts were available. He emphasized the lack of persistence and want of definition exhibited by the veins of the district, and concluded that "these irregular reefs represent the horizontal sections of columns of rocks traversed by rising columns of hot waters. . . . It follows that the quartz bodies will probably, as a rule, extend deeper vertically than horizontally, and so have roughly the nature of columns or pipes." No one would recognize in these generalizations any description of the ore deposits as exposed today. Mr. Spurr has done such splendid work at Tonopah and Silver Peak, that it is surprising he should have so ill interpreted Goldfield. Undoubtedly he was the victim of that haste of publication to which the Survey is occasionally committed in the desire to please the politicians and other local powers that clamor for geological reports even before the necessary evidence is contributed by actual mining.

The next scientific investigation was made about a year later, by F. L. Ransome, who was at Goldfield at the end of 1905 and the beginning of 1906. His report appears in Bulletin No. 303 of the Survey. This work was less sketchy, although preliminary. Enough evidence was collected to warrant the comprehensive and illuminating statement that the district covers a domical uplift of Tertiary eruptives resting upon highly altered sedimentary rocks of probably Paleozoic age. This appears to be the key to the correct understanding of the local geology. In February, 1906, John B. Hastings and Charles P. Berkey contributed a valuable paper on the geology and petrography of Goldfield to the Transactions of the American Institute of Mining Engineers. This paper is often quoted by the local mine managers and it contains much useful information. The identification of the chief rock-types shows results varying slightly from those of Mr. Ransome and bearing a closer resemblance to the rocks of Tonopah. Hastings emphasizes the extreme silicification of the eruptives along systems of fracture and the evidence of wide-spread solfataric action.

The most recent description of Goldfield geology will be found in an excellent article on the Combination mine, written by Edgar A. Collins, and published in the MINING AND SCIENTIFIC PRESS of September 28 and October 5, 1907. This gives a detailed account of underground exploration by the manager of the mine that first made Goldfield famous.

When F. L. Ransome made his preliminary investigations more than two years ago, the great bonanzas had not been discovered and Goldfield gave no signs of its recent prominence as a mining district. Since then, I am informed, there has been a disposition to discourage further scientific examination by the Government geologists because of litigation as to mineral rights between different mining companies. The completion of the big merger of many of the principal mines has removed several likely points of dispute, but even now two or three important suits are pending, involving questions of extra-lateral right, and while I was at Goldfield I found Horace V. Winchell, W. H. Wiley, Charles J. Moore, and other mining geologists engaged in collecting evidence to serve as ammunition in the courts. The law is not always synonymous with justice, nor is

Glory Hole of the Combination Mine.

mining litigation necessarily a stimulant to the ascertainment of scientific facts. Too often these quarrels over mining territory breed a bastard sort of theory and in any event the effect of them is to silence the men best able to contribute to our knowledge of local geology. So, for the present, there is not much more to be said than that the prevailing rocks are Tertiary eruptives forming a low dome over a core of much older metamorphic sediments.

As is usual in ground that has undergone intense mineralization, the structure of the orebodies is indefinite. Obvious boundaries and simple definition are more likely characteristics of poor lodes than of rich ones. Diffuse impregnation with ore tends to obscure the relation between the vein and the rock it traverses. The prevailing rock is dacite, which has a porphyritic habit by reason of phenocrysts of feldspar. This feldspar is labradorite; in fresh dacite it

is white to pale green; by alteration to alunite it becomes pink. The dacite is essentially a quartz-andesite. This is the rock in which most of the rich ore is being found. It is covered by patches of 'wash,' or débris, so that the surface exposure is incomplete, but enough evidence is available to indicate that it extends over the principal portion of the rolling plain occupied by Goldfield. Several knobs, such as Columbia and Vindicator mountains, appear to thrust themselves through the dacite, but they are really older masses that have survived erosion. They represent cores of hard calcareous shale (of Cambrian age) flanked by alaskite and rhyolite. The dacite is broken by several faults, the most important being to the west of the bonanza ground

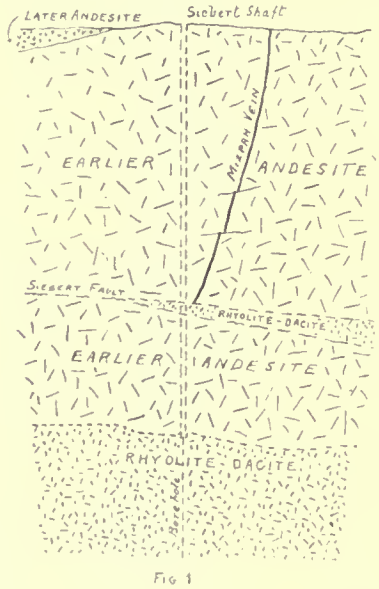

FIG 1

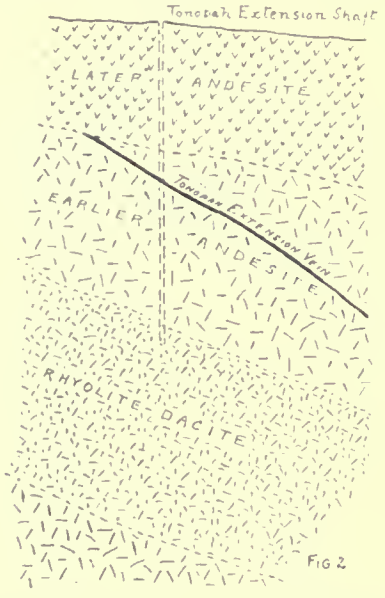

FIG 2

and apparently limiting it in that direction. West of the fault the rock is an earlier andesite. The thickness of the dacite is not known; the deepest workings, at 600 ft. in the Mohawk, are still in this formation. On the bottom level of the Combination (380 ft.) some andesite appears under the dacite, the andesite dipping about 34° northeast. The relation between the two formations is a matter of importance, for if ascertained it would answer the question whether the dacite is an intrusion or a thick layer. At Tonopah the petrography proved the key to the mining geology in an unexpected way, as the accompanying sketches[1] illustrate. Fig. 1 shows the Mizpah vein traversing an earlier andesite and cut off by an intrusion of later rhyolite-dacite; while Fig. 2 shows the Tonopah Extension vein, which does not penetrate the later andesite and fails to reach the present surface. By reference to Fig. 1, it is seen that the Mizpah vein just missed being covered by the later andesite (shown to the extreme left of the section) and so yielded an outcrop the richness of which led to the development of the Tonopah district. It is evident that the veins were formed during a period intervening between the extrusion of the two andesites. It is likely that the deposition of ore was a sequel to the thermal activity that followed the extrusion of the older andesite.

At Goldfield the ore was found at the surface as an enriched portion of one or two ridges of quartzose rock. These ridges were combs formed by the silicification of the dacite along lines of fracture. In the rich area the chief lines of fracture run nearly north and south, and they are marked at intervals by

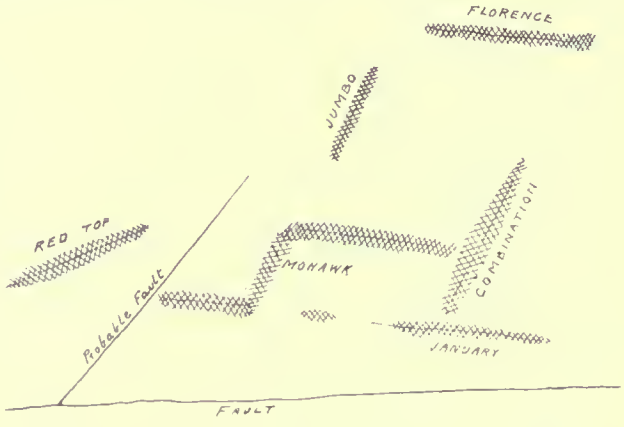

Fig. 3. Sketch Showing Relative Position of Orebodies.

these outcrops or 'blow-outs' of silicious rock. Most of them are poor, if not barren, and it was only on the Combination, January, and Jumbo that the early prospectors were able to find pay-ore. Most of the orebodies were discovered by haphazard sinking of shafts and cross-cutting into these same masses of silicified dacite at a lower level. For instance, Hayes and Monette, in their famous lease on the Mohawk, struck the first ore by cross-cutting at 150 ft. They cut it at 25 ft. from their shaft. The finest showing was just below the 150-ft. level, where they had two feet of ore assaying $15,000 per ton. This was a black heavy sulphide streak, from one inch to two feet wide; it persisted with regularity for 130 ft. on the dip. The lessees extracted a lot of 49 tons that assayed $6.50 per pound. The bottom of the zone of oxidation was between 105 and 115 ft. below the surface. In the Mohawk ground the pay-ore usually did not extend into the oxidized zone, but in the Sheets Ish and the Combination it reached to the surface.

The accompanying sketch shows the distribution of the principal orebodies as known today. It suggests that there is a system of co-ordinate fractures, which are not exactly at right angles. The north-

[1] 'Geology of the Tonopah Mining District,' J. E. Spurr, U. S. G. S.

south members dip east from 34 to 50°; along them are found the Red Top, Mohawk, Florence, and part of the January lodes. The east-west (or more accurately, west of north) members are nearly vertical, for example, the Combination and the Jumbo. At the intersections of these lines of fracture there has been intensified mineralization, which has been supplemented by faulting, followed in turn by another period of ore deposition, leading to further enrichment. By faulting, the co-ordinated fissures have been shifted so as to accentuate the multiplicity of fracturing and assist mineralization. The lode-channel thus formed has been dislocated in many places by cross-faults but the rich streaks within the lode-channel appear only to have been diverted, that is, the later enrichment following the fault-lines. In the hard silicious mass of the lode-channel the faulting is easy to follow but in the soft outer country it is difficult to trace. Minor movements complicate the structure, especially within the larger orebodies. It is dangerous to label the individual veins and to try to trace them for any distance; they lose their identity and become part of a larger linked system. Bulges and violent changes of strike in the veins and in the main hanging wall of the lode-channel suggest an end-thrust, causing a buckling of the dacite. The best ore is found in the bulges, reaching in places from hanging to foot-wall for the full width of the lode-channel, that is, 500 to 300 ft. Thus splendid orebodies have been found. In the Mohawk the rich ore is continuous for 800 ft., and in the Combination for 500 ft., reaching out to 1000 ft. The deepest working is the winze below the 450-ft. level in the Mohawk; this is down 160 ft. on the dip, or within 50 ft. of the 600-ft. level. This winze, 8 ft. wide by 12 ft. long, has already yielded $75,000 worth of ore, and as much more is in the bins. The average has been $135 for a minimum of 6 ft. and a maximum not yet ascertained, as it exceeds the width of the winze. This is an encouraging fact, and while deeper development may at any moment break into the older andesite supposed to exist under the dacite, it is apparent that the depth already proved leaves ample room for the existence and exploitation of extensive orebodies.

The lode-channel has become, by silicification, harder than the surrounding country. If you walk into a cross-cut and see ahead some white rock fallen from the roof, you know that at that point the cross-cut has passed into the outer dacite. But while the lode-channel as a whole is hardened by silicification, the best ore is along lines softened by intense chemical action, resulting among other effects in the formation of seams and patches of the white substance called 'tale' by the miners. It is mainly alunite, a hydrous sulphate of aluminum and potassium.[2] Hugh Trenholm, superintendent of the Red Top, told me that this 'tale' is a good sign, especially when gritty. The rich ore is usually a seam of dark chalcedonic quartz, carrying needle-shaped crystals of bismuthinite (bismuth sulphide), together with gray copper, pyrite, and occasionally tellurides, such as calaverite.[3] This rich stuff is commonly flanked by mineralized and silicified rock rich enough to be classed as ore. The gold itself is not easy to see, even in the richest ore, until the specimen is wetted; then it is seen in dull yellow bands formed by minute particles of gold arranged along lines of crustification. The gold is like paint, if you please, but unlike that of Kalgoorlie, which was soft, as metal newly precipitated from solution, and required to be scratched to be detected. The burnishing developed the yellow-red glint of the noble metal. At Goldfield the gold is fine, but crystalline, and therefore quite different from the 'mustard gold' of Kalgoorlie. It appears to have been deposited with the chalcedonic quartz, which it ribbons. The gold is sufficiently free to permit of the use of the pan in ascertaining what is rich ore. Mr. Collins states that it was impossible "to tell pay-ore from worthless vein-stuff by its appearance," but panning served as a trustworthy guide. Visible gold was most abundant in the Mohawk ore after a depth of 300 ft. below the zone of oxidation had been attained, that is, over 400 ft. altogether below the surface. Some handsome specimens of free gold were extracted in the winze, at 50 to 70 ft. below the 450-ft. level, and these were identical with specimens broken in the Florence mine. The Florence is a smaller, better defined vein than the Mohawk, and I expect to see the latter become smaller and more clean-cut in depth when once below the horizon of maximum enrichment, just beneath the zone of oxidation. In the Florence a 3-ft. stope suffices; the ore thus broken in the Little Florence lease has averaged $200 to $250 per ton, down to 400 ft., where the orebody pitches into adjacent ground. It is said that 5200 tons have been shipped from this lease for a gross yield of $1,250,000. The rich streak is usually only a few inches wide; the vein is well-defined and reminded me of some I had examined in Boulder county, Colorado.[4] The Florence orebodies are not long, say 75 ft., and in some cases isolated masses of rich ore have been found in the foot-wall country, at the intersection of fractures. One of them, at the 400-ft. level, was 12 to 15 ft. diam., 70 ft. high, and roughly egg-shaped.

The mine managers speak of a hanging and a foot-wall, meaning thereby the eastern and the western limit of their exploration, for in the Red Top, I saw good stopes on a vein beyond what was once called the hanging, and a rich vein (several feet wide) beyond what was formerly regarded as the foot-wall. These 'walls' are marked by a selvage of clay, they are lines of faulting and lose themselves in other slips and gouge-seams. The most persistent of the eastern 'walls' in the Mohawk is called the hanging; it rolls both in strike and dip, so as to form large bulges, as if the lode-channel had been crumpled by pressure from the north and south. Rich ore is found within these bulges and across them, as well as along the principal 'walls'.

Every observant visitor to a new and very rich mining district wonders whether the orebodies will

[2] 'The Association of Alunite with Gold in the Goldfield District, Nevada,' by F. L. Ransome. *Economic Geology*, Vol. II, No. 7.

[3] Telluride minerals are rarely visible. In two analyses of a concentrate obtained from a mill-test on Mohawk and Combination ore, the following results were obtained: The first analysis gave 0.25% Te and Se, with 41.5% S; the other gave 0.27 Te% and Se, with 42.69% S. The concentration was in the ratio of 39 to 1, and about two-thirds of the sulphur went into the concentrate.

PRELIMINARY GEOLOGIC MAP OF THE GOLDFIELD DISTRICT.

United States Geological Survey. F. L. Ransome, Geologist.

persist. Facts are wanting wherewith to base any conclusion as regards the future of Goldfield. In the big mine—the Mohawk—there is a length of 600 ft. of ore proved on the 350-ft. level; at 450 ft. there is 300 ft. of ore known to exist, but there is promise of 500 ft. of stoping ground on the main orebody. Below the 450-ft. there is only the winze, which has been sunk 160 ft., in the heart of the orebody and with the most encouraging results, as already stated. Owing to the dip, each 100 ft. of vertical depth gives 140 ft. on the lode. A body of ore 500 ft. long, 140 ft. high, and 12 ft. wide, represents 64,000 tons, and this at $50 per ton, means over three million dollars. But the estimation of ore reserves at Goldfield is a tricky problem. It is always difficult where ore is rich and variable within wide limits. A careful man will be more willing to assert his ability to maintain a certain production for a minimum period than to commit himself to a statement of ultimate profit.

Since my visit to the Mohawk, the lode has been cut on the 600-ft. level in a cross-cut at a distance of 380 ft. east of the main shaft. Measured at right angles to the dip, the ore is slightly over 20 ft. wide, and the average of 51 sectional samples is $51.50 per ton. There is a central core of 8 ft. of stuff that averages $75, with a gradation in value toward each wall. The cross-cut is being continued eastward and is going through lode-matter assaying from $1 to $4 per ton. When the dacite of the hanging wall is reached, a drift will be started each way on the ore. Another favorable development is the finding of ore on the 380-ft. level of the Combination, where four feet of $35 to $40 stuff has been exposed, with no foot-wall as yet in sight. It is a pleasure to chronicle these happenings, as well as a promising discovery on the Laguna ground. No mining engineer of any experience can go through the workings of the Consolidated group of mines without being impressed by the large amount of rich ore, the unsystematic way in which it was worked by the former lessees, the difficulty of estimating the ore reserves, the possibilities of further discovery, and the evidence of widespread enrichment. But as surely as you do not know how much ore there is in a mine, so surely you are likely not to know how little there may be, and no thoughtful man can fail to regret the huge capitalization of the Goldfield Consolidated Mines Co., with its nominal capital of $50,000,000, its issued stock of $35,351,710, and its present market valuation of $21,000,000. Geological possibilities are not liquid assets.

A topographic map of the Controller Bay region, Alaska, issued by the U. S. Geological Survey, is ready for distribution. The map covers an area of 430 square miles, lying 1250 miles northwest of Seattle and 400 miles northwest of Sitka, and includes the entire area of the Bering River coalfield and the Katalla oilfield. Katalla, the most important town in the area mapped, will be the tide-water terminal of two railroads now under construction. The map will be sent to any address for 35c. on application to the Director of the Survey, Washington, D. C.

The Prospector.

Owing to the large number of specimens forwarded to this department, it has been found necessary in future to make a charge of 25 cents to subscribers for each determination, and $3 to non-subscribers.

From D. H. P., Hamilton, Nevada, a glassy volcanic ash, showing plainly lines of stratification and cross-bedding.

Received from R. S., Kellogg, Idaho, a disintegrated granite re-cemented without much transportation of constituents; an arkose.

From R. D., San Francisco: The specimen of coarser grain is a much weathered phase of an argillaceous sandstone; the finer grained specimen, a schistose phase of a sandy shale.

From F. G. C., Lordsburg, N. M.: 1, iron pyrite; 2, a specimen too small to determine whether vein matter or a metamorphic rock composed of quartz, chlorite, serpentine, and calcite in veins and as an interstitial filling, all impregnated by pyrite; 3, an impure quartzite veined by calcite; 4, granite, possibly gneiss, impregnated by pyrite.

From J. P. C., Cuprite, Nevada: 1, drusy aggregate of calcite crystals in vein in impure limestone; 2, shale; 3, shale, with flakes of muscovite; 4, quartzite veined with calcite; 5, quartzite; 6, quartzite seamed by veins of hematite; 7, fine-grained sandstone with calcite-limonite cement; 8, sandstone with calcite-limonite cement showing scales of specular hematite; 9, medium-grained sandstone with lime-iron cement; 10, argillaceous limestone with nodules of iron carbonate; 11, sandy shale with veins of siderite; 12, quartzite, or possibly vein quartz (small specimen; 13, rhyolite; 14, druses of quartz and calcite crystals coated with hematite, in quartz, limonite rock.

From B. DeL. Gold Mines Co., DeLamar, Nevada: all specimens highly decomposed by weather, and consequently difficult to classify precisely: 1, fragmental acid volcanic tinted pink by hematite, a rhyolite tuff, or possibly a dacite tuff; 2, rhyolite tuff; 3, pyritized acid volcanic, probably from rhyolite tuff; 4, rhyolite; 5, rhyolite tuff, extremely weathered; 6, fine-grained kaolin limonite aggregate with a little quartz, structure indeterminate, derived from rhyolite or andesite; 7, coarse rhyolite tuff; 8, acid tuff, some quartz; 9, rhyolite; 10, rhyolite tuff, reddened by hematite; 11, quartzose rhyolite tuff; 12, a tuff weathered to an extreme degree, traversed by veins of chalcedony and manganese oxide; 13, acid volcanic made very porous by leaching, leaving pore-walls coated with oxides of iron, with pyrite and manganese oxide in small quantity.

The largest gold production ever credited to California was $81,294,700, in the year 1852. The lowest production since 1850 was in 1889, when it was $11,212,913. For the past 12 years it has ranged between $12,000,000 and $17,000,000.

COPPER DEPOSITS IN THE WESTERN FOOTHILLS OF THE SIERRA NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By WILLIAM FORSTNER.

These deposits have been the subject lately of three articles; one by Herbert Lang in *The Engineering and Mining Journal* of November, 1907, and two by John A. Reid, in *Economic Geology*, Vol. II, No. 4, and in the MINING AND SCIENTIFIC PRESS, March 21, 1908. As I had occasion, a couple of years ago, to examine a number of deposits of copper in this region, I venture to present a general description of the belt, with such a short description of some of the deposits as will emphasize the geological conditions.

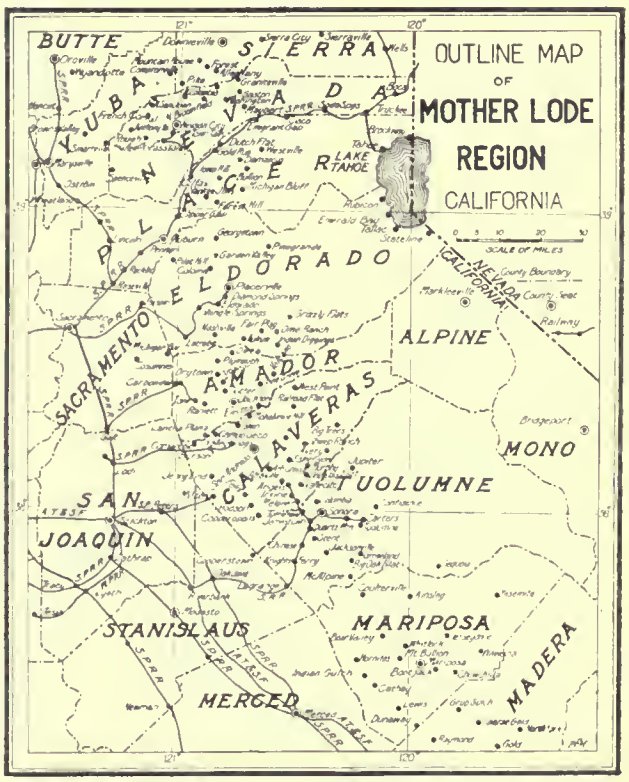
Description of Rock Formations.

Granodiorite is a term applied by the U. S. Geological Survey for the intermediate rocks between granites and quartz-diorites. The rock is distinctive and cannot easily be mistaken. The feldspars are generally white, the quartz is not conspicuous and does not occur in large grains; the hornblende is dark green, often in long rough prisms; the biotite has the usual dark color. The general effect is a light-gray color.[1] Where the granodiorite has been rendered schistose, it is converted into a grayish-green rock, breaking into flat irregular fragments, bounded by smooth greenish faces, with greasy feel.[2] It weathers with rounded outcrops (Smartsville folio, U.S.G.S.).

Gabbro-diorite comprises several species of rocks: normal gabbro, norite, hornblende-gabbro, olivine-gabbro, all frequently altered into uralite-gabbro; and also dark basic diorite. They are generally coarse-grained rocks of dark color. These rocks generally occur near the contacts of the large granodiorite areas, and are separated from the latter, sometimes by sharp contact, sometimes by gradual transition.

These granodiorite and gabbro-diorite areas represent geologic units intruded and consolidated within a relatively short time interval (Smartsville folio).

The term 'porphyrite' has been applied to pre-Tertiary andesites, and as such is applicable to these rocks, which are of pre-Cretaceous age. In the older folios of the Survey this term was used throughout for a complex of rocks occurring along the western foothills of the Sierra Nevada in long belts, generally parallel with the belts of sedimentary rocks between which they lie. They are poor in silica, rich in iron and magnesia. This series includes several species of rocks so intimately connected by transitions that it is not as a rule possible to subdivide them in the field. It comprises medium-grained diabases, augite-porphyrites, hornblende-porphyrites, and breccia and coarse and fine tuffs of the same rocks. These rocks are frequently altered into uralite-diabase and uralite-porphyrites. They are often designated under the collective term of the 'greenstone' series. The relations of this series to the sedimentary series are not established beyond doubt. Probably these rocks should be regarded as intrusive, and not as interbedded masses. As to their age, it is probable that these rocks were erupted both in the Carboniferous and in the Jurassic period; they are intruded into the Carboniferous formation and may represent surface flows contemporaneous with the Jura-Trias slates, and intrusive dikes into them, as both forms of eruption are known in connection with the Mariposa formation. The relation of the diabase, porphyrite, and amphibolite with the granodiorite is not quite clear. In the Sacramento and Sonora folios, the granodiorite is stated to be intrusive and of later age than the inclosing amphibolite and augite-porphyrite; in the Colfax folio, although relating to a region not included in this paper, it is stated: "The general rule holds good that the main granitic area is more recent than the greenstones . . ." In the Smartsville folio, however, it is said: "The contacts



of the diabase-porphyrites with the granodiorite and gabbro-diorite are sometimes exceedingly sharp, . . . sometimes ill defined . . . In many cases it is difficult to avoid the conclusion that a gradual transition exists between the granodiorite and the diabase." And further: "In the mixed granodiorite and gabbro-diorite areas of the central part the evidence along the contacts is that both rocks are cut by an abundance of diabase and porphyritic dikes usually uralitized, and which appear identical with the porphyrite and the diabase of the main area. Thus at least part of these are later than the gabbro and granodiorite." And again: "The general sequence of the Mesozoic eruptions would thus seem to have begun by the intrusion of gabbro-diorite and granodiorite, followed by extrusion of great quantities of diabase and porphyrites; and larger intrusions of granodiorite ended the eruptive activity."

The altered igneous rocks are generally derived from augite-porphyrites and similar rocks, although occasionally from diorites and gabbros, under the

[1] W. Lindgren. *Am. Journ. of Science*, Vol. 46, 3rd series.
[2] W. Lindgren. 17th *Annual Report*, U. S. G. S., Pt. II, p. 145.

influence of pressure and chemical action, which cause the augites to alter into amphiboles (in part uralite), and the whole rock to be filled by minute needles of that mineral. This green amphibole is a characteristic mineral of these rocks: quartz, plagioclase, feldspar, chlorite, epidote, biotite, white mica, and calcite, in varying quantities are also present. The derivation of these rocks from rocks of diverse chemical composition and texture is clearly shown by actual transitions in the field. Their color is dark green; usually fine-grained with plentiful small amphibole needles. They are often sheared amphibolite schists, locally known as 'greenstone-schists,' or 'gray slates.' In places the schists become chloritic and are sometimes difficult to distinguish from clay-slates. As to the age of these altered igneous rocks, see under porphyrite.

In the Smartsville folio the serpentine is stated to be an alteration of some of the most basic rocks of the gabbro-diorite complex. In the other folios it is marked as intrusive in the porphyrite and as possibly an alteration product of the diabase, porphyrite, and amphibolite. All these statements tend to the conclusion that it is of later age than the diabase-porphyrite.

The Calaveras formation is a complex of Paleozoic rocks with so little connection with the copper deposits that it needs no further discussion. The Mariposa slates are black, very fissile, clay-slates, interstratified with fine and coarse tuffs, dark gray sandstones, and conglomerates; their age is late Jurassic.

General Geology.

In the region here under consideration, there is a wide belt of diabase, porphyrite, and amphibolite skirting the eastern rim of the Great Valley, and intersected by large masses of granodiorites, running from the Yuba river in a southeasterly direction, and abutting to the east against the Calaveras formation. From the American river near Folsom, southward, the granodiorite exposures become much less prominent. A little south of Folsom is the northern extremity of the western belt of Mariposa slates, which continues, enclosed in the 'greenstone' belt, in a southeasterly direction to the southeastern part of Mariposa county, running conformably to the general structure of the entire region. In El Dorado county, as far as I know, the copper deposits are confined to that portion of the greenstone belt lying east of the western belt of Mariposa slates, while in the counties south of El Dorado they are found on both sides of this belt.

In Madera and Mariposa counties, the Mariposa slates show the effects of contact metamorphism, and are to a large extent altered into mica-schist and andalusite-schist. The granitic rocks become again a predominant feature and increase in importance southward. The derivation of the mica-schist in Fresno county is, as far as I know, an open question.

The western belt of the Calaveras formation, which is quite massive south of the north fork of the American river, does not show so prominently farther northward; one narrow tongue runs north, continuous to about a mile south of the south fork of the Yuba river, northwest of Nevada City. To the west, however, especially on both sides of Bear river, small exposures of the Calaveras are found in the diabase-porphyrite, almost to the Pleistocene gravels of the valley. The most rational conclusion to be drawn is that the diabase, porphyrite, and amphibolite represent effusives which were extruded through the Calaveras, and covered the latter formation.

In Nevada and Placer counties, the foothills consist nearly exclusively of the diabase-porphyrite, amphibolite, and the granodiorite-gabbro-diorite.

In Nevada county, a number of copper deposits are found near the contact of the diabase-porphyrite and the extensive granodiorite and gabbro-diorite area, running from Iron mountain north to Challenge in Yuba county. Most probably the copper deposits near French Corral are on the same contact. The relation between the diabase-porphyrite and the granodiorite and gabbro-diorite has been discussed above. Assuming that in this locality the porphyrite is the youngest rock, there is no doubt that it was much fractured near the contact-zone, and as all the deposits of copper ore are found in the porphyrite, and none in the granodiorite, or in the basic dikes intruded therein, the conclusion is inevitable that the source of the copper-bearing solutions must be sought in the magma of the diabase-porphyrite effusions.

South of Bear river, the ore deposits are found in the diabase, porphyrite, and amphibolite, but apparently have no genetic relation with the granodiorite intrusions; in this statement must be included the deposits at the Nickerson ranch, Nevada county. These deposits are possibly related to intrusions of dikes of various chemical composition, with only small surface exposures; and for the more eastern deposits, Oest ranch and Nickerson ranch, to the intrusions of peridotite and pyroxenite, partially altered to serpentine, running from Auburn to Grass Valley in intermittent exposures and closely related to the western band of the Calaveras formation.

In Mariposa and Madera counties, the copper deposits are found in mica-schist and andalusite-schist, which may be alteration facies of the Mariposa slates. The Pool mine in Calaveras county is also in the Mariposa slates.

Nevada County.

The Mineral Hill district is situated on Dry creek, between Smartsville and Spenceville. A number of prospects are located in this district in close vicinity to each other. The country rock is diabase-porphyrite, altered to a variable extent, partially serpentinized, and in places rendered schistose. All the rocks carry disseminated pyrite; the portions, sufficiently mineralized to form ore, are apparently zones of fracturing of the rock, in which are often found segregations of quartz. There are several more or less parallel zones of fracturing, having a northwest strike and northeast dip, accompanied by occasional faulting. In and near these fracture-zones the rock has a schistose structure, the planes of schistosity parallel to the direction of the fracture-zones; in the intervening areas the rock is more massive, with a blocky structure. As a general rule the schistose

rock contains much more disseminated pyrite than the massive portion.

The mineralization has taken place through replacement of the silicates of the porphyrite by pyrite, often in the form of marcasite, bornite, chalcocite, and covellite; the last three being found in the zone of secondary enrichment. In one mine, the Arkansas Traveler, vugs with incrustations of quartz and pyrite were observed. Occasionally quartz deposition without accompanying pyrite deposition is found. A number of outcrops exist, in most cases not continuous far, although this cannot be ascertained as the hillsides are covered with débris. Where developed underground these outcrops have been proved to be underlaid by sulphides. In former years only the rich ore could be mined; it was confined to the zone of secondary enrichment. From what is disclosed in the accessible workings I conclude that the orebodies are not continuous, but have formed in such portions of the zones of fracturing, determined by the talcose planes resulting from movement.

The Pine Hill mine is in the diabase-porphyrite to the south of the granodiorite-gabbro-diorite area. In this property the underground works show a great amount of clay, which would suggest the presence of some highly feldspathic rock, although the vein-filling is apparently a more basic rock. There is a possibility that the ore is formed in the diabase-porphyrite, between two quartz-porphyry intrusions close to each other. The gossan must have been pretty rich in precious metals, for the mine was in former years extensively worked for gold.

The Indian Springs mine is situated east of the Mineral Hill district. Croppings abound on this property, the country rock carries disseminated pyrite and weathers with purple and ochreous colors, giving it a likeness to limonite, which must be differentiated from the true limonite croppings. The latter form two zones, having a general north and south direction. The surface is decomposed to a depth of 40 ft. into an ochreous clayey material. The ore consists of rather coarse brittle pyrite with some silica. The texture of the ore, which is a replacement product, would indicate that the original rock in which it formed was of a character different from the country rock; this is confirmed by the texture and composition of the filling between the ore, and leads me to the suggestion that more basic dikes have intruded into the country rock and formed zones of circulation for the mineral-bearing solutions, which replaced part of the silicates of these intrusions by sulphides.

The Nickerson ranch is on Wolf creek, near its junction with Bear river. The ore deposits form in diabase-porphyrite, on both sides of a narrow belt of Calaveras formation, which in turn is separarated into two parts by a serpentine intrusion. The matrix of the ore is quartz, heavily charged with pyrite; the ore occurs in elongated lenses. As the serpentine is generally conceded to be later than the porphyrite, it is possible that the ore deposits were due to the fracturing of the porphyrite by the serpentine intrusion.

Placer County.

The Dairy Farm mine is in the northwest part of this county, about one mile south of the McCourtney crossing of the Bear river, on the contact of diabase-porphyrite to the west and amphibolite-schist to the east. The schist is much altered and in the zone of oxidation forms a white clayey material. It differs to a certain extent from the facies of true amphibolite-schist, and may probably be an altered quartz-porphyrite (a more silicious porphyrite, often closely related to the ordinary porphyrite, consisting of porphyritic decomposed feldspar crystals and decomposed augite and hornblende, in a light-gray flinty ground-mass of small feldspar crystals and quartz grains, and containing frequently much epidote).[3] This schist forms the hanging wall, the diabase the foot-wall. In both formations occur small elongated lenses of quartz-porphyry. As to the genetic relation of these quartz-porphyry intrusions to the ore deposition, their intrusion certainly fractured the rocks, and although probably the ore-bearing solutions found their source in the diabase-porphyry magma, as was the case with those in Nevada county, only a few miles to the north, they possibly afforded conditions favorable to ore deposition. The granodiorite, a little over a mile west of the Dairy Farm mine, is intruded into the diabase-porphyrite, and hence younger than the porphyrite, but whether this granodiorite and the quartz-porphyry are younger or older than the ore deposition is an open question.

The orebody in the Dairy Farm mine forms a large lens. The ores are the result of replacement in a zone of fracturing; all through the orebody the planes of fissuring can be seen, roughly parallel to the planes of schistosity of the hanging-wall schist. Plates of unmineralized, or only partly mineralized, schist run through the orebodies. On the contact of the oxidized zone and the sulphide zone the transition occurs suddenly, with scarcely any of the secondary copper sulphides generally found in the upper portions of the sulphide ores.

The Valley View mine is located six miles northeast of Lincoln and about the same distance east of south of the Dairy Farm mine, in the same belt of amphibolite schist as the latter, close to the contact of a large area of granodiorite. Two intrusive dikes can be traced on the surface.

The Oest ranch, about 6½ miles north of Auburn, on the road to Grass Valley, is a copper deposit in typical porphyrite, altered andesite, carrying disseminated pyrite. The fractures of this rock are refilled by quartz containing thin seams of siderite. In the gangue is found some serpentine. The belt of porphyrite in which these deposits lie is about one mile wide, between the Calaveras formation to the west and a boss of granodiorite to the east. The Calaveras forms a narrow band and is accompanied by a belt of pyroxenites, peridotites, and serpentine. These intrusives may have a genetic relation to the ore deposition.

El Dorado County.

The Baker mine is located about 2¾ miles south of Placerville and 1½ miles east of Diamond Springs, in a belt of Mariposa slates, cut by a number of small dike-like intrusions of granodiorite. The fis-

[3] Colfax folio, and *Bulletin* 139, U. S. G. S., page 97.

sures cut the slates at acute angles, both in dip and strike. Probably the vein filling is formed by narrow intrusive dikes of granodiorite, altered to a more or less extent into copper-bearing pyritic ore.

The Lily-Emma mine is situated on Halsey creek, about two miles above the south fork of the American river, and about six miles northeast of Coloma. The country rock contains augite and garnet and secondary chlorite, and might be considered a pyroxenite. A dike of fine-grained peridotite apparently cuts off the mineralization to the south. The ore consists of quartz with calcite and chlorite, and contains patches of pyrite associated with chalcopyrite. It has undoubtedly formed in a fractured zone of the pyroxenite.

The Noonday mine and smaller deposits in its vicinity are 3½ miles east of south of Mud Springs and on the east bank of Square Hollow creek. They are in a belt of the Calaveras formation. In the Noonday the vein is conformable with the dip and strike of the country rock, the ore is highly pyritic, containing little silica. I observed no signs of any intrusions at the surface in close proximity to the mine. In the Madeline, a little more than half a mile to the south of the Noonday, the vein abuts against a basic dike, containing inclusions of pyrite associated with chalcopyrite and traversed by numerous veinlets of quartz, which is occasionally replaced by similar pyrite.

These deposits in El Dorado county are all east of the belt in which the deposits of Nevada and Placer counties are situated. In the southeastern portion of El Dorado county lies a wide belt of amphibolite and diabase-porphyrite, between Mariposa slates to the west and the Calaveras formation to the east, in which numerous exposures of serpentine occur; this belt persists southward into Amador county. Numerous deposits of copper have been found in this belt; none, however, have been developed sufficiently to pass the stage of prospects.

Calaveras County.

The Campo Seco mine is on the south bank of the Mokelumne river, about 4½ miles west of north of Valley Springs, in the amphibolite schist lying west of the main western belt of the Mariposa slates. The orebodies form in two intrusive dikes of quartz-porphyry, running nearly parallel to the planes of schistosity of the schist, and from 125 to 200 ft. wide. These intrusives are highly altered, to a great extent into a very soft, talcose, thinly laminated schistose material, through which runs a belt, about 50 ft. wide, of much harder, quartzose schist, carrying disseminated small crystals of pyrite, with bands from ⅛ to 2 and 3 in. wide of quartz containing pyrite and chalcopyrite. In places, approaching the ore lenses, these seams come close together and form seams from 18 in. to 2 ft. wide. These narrow bands widen abruptly into lenses, which are in dip and in strike, in a general way, conformable with the schistosity of the intrusive. The lenses are much elongated in the direction of their strike, their longest axis is along their dip, and they trend northward along the strike. As far as ascertained there are no parallel belts of quartzose material in the intrusive dikes, and hence no parallel ore-shoots across the dikes.

The ore consists of massive pyrite, with accessory chalcopyrite, sphalerite, gold, and silver. It grades into the enclosing intrusive, and inclusions of the quartz-porphyry are occasionally found in the lenses. There is a marked difference in the character of the mineralization of the two dikes, as to the relative contents of iron, copper, zinc, gold, and silver. In each lens the content of ore is also irregular.

The planes of schistosity in the dikes, the general trend of the dikes, and the planes of schistosity of the enclosing schist are all parallel; evidently all three are the result of the long sustained orogenic pressure which controlled the deformation of all the formations in this region. The position of the ore lenses must have depended upon the physical condition of the dikes, forming in those portions of the quartzose belt that were most favorable to replacement.

As to the genesis of these ores, all indications tend to the suggestion that they are related to the quartz-porphyry intrusions, and are later than the movements causing the schistosity in the latter, which forms the talcose portions that acted as impervious strata and restricted the mineralized solutions to the harder fractured portion.

The Copperopolis mine lies in that portion of the greenstone belt which is east of the western belt of the Mariposa slates. This deposit has been very fully described by John A. Reid, as already mentioned. According to his description, this deposit forms in a chlorite schist facies of the diabase-porphyrite, close to intrusions of serpentine, a very basic igneous rock, classified by Mr. Reid as hornblendite, granodiorite, and gabbro. The ore forms in numerous minute fractures of the chlorite-schist; its grade depends upon the intensity of fracturing of the schist, the veinlets vary from $^1/_{16}$ to 3 and 4 in. wide. The ore is a mixture of pyrite and chalcopyrite, grading in the richer ore to nearly pure chalcopyrite. Mr. Reid suggests that the separation of the copper-iron and iron sulphides is the result of osmotic pressure, and incidentally accounts in the same manner for the occurrence of pure iron pyrite in the wall-rocks of various gold-bearing ore deposits. The part played by osmotic pressure as a factor in ore deposition is as yet a matter of controversy. H. P. Gillette[4] states as his opinion "that when the solutions are filling the crevices and small interstices in the fissures, there is a concentration of the dissolved material along the walls of these crevices and interstices, due to osmosis, this concentration causes precipitation, and again due to osmosis new particles of the dissolved material is brought to these points, resulting in enlargement of deposited crystals." Mr. Gillette bases his reasoning upon the following determination of the term osmosis: "Osmosis is a force which drives a solute through a solution." I doubt if this determination fully covers the case: as W. Nernst says, the osmotic pressure is due to "the tendency of the molecules of the dissolved substance to occupy the greatest possible space." T. K. Rose states: "Os-

[4] *Trans.* A. I. M. E., Vol. XXXIV, page 711.

motic pressure is a measure of the bombardment of molecules of substances trying to diffuse in a solution." I see nothing in osmosis to cause a concentration of the molecules of the dissolved substance "at the extreme confines of the vessel holding the solvents." Adsorption (that is, the phenomenon whereby in contact-surfaces between solids and liquids, the concentration of the dissolved substance is different from, and usually larger than in the rest of the solution) may take place, and osmosis may restore the equilibrium in the solution thus disturbed. As James Park states, "The osmotic pressure will, if precipitation takes place from a homogeneous solution, instantaneously establish a condition of equal concentration throughout the entire mass." It must be further observed that the osmotic pressure is a function of the concentration, and consequently if one of the dissolved substances was deposited, its osmotic pressure would rapidly decrease.

As to the action of chlorite acting as a semi-permeable septum, impermeable to copper and permeable to iron in solution also suggested by Mr. Reid, I have been unable to find any confirmation. W. Lindgren states with regard to this action of the minerals of the rocks: "They are in general shown to be permeable for hydrogen sulphide, sodium sulphide, or arseno-sulphide; on the other hand, they are less permeable for silica and gold, and almost entirely impermeable for the other metallic sulphides." This certainly is in direct contradiction to the suggestion of Mr. Reid in regard to the formation of pyrite barren of gold in the wall rocks of gold veins carrying gold-bearing pyrite. It is, however, possible that Mr. Reid may be in a position to state many facts bearing upon this question which would confirm his hypothesis; and a paper covering the present status of our knowledge on the subject of the influence of osmotic pressure on ore deposition would certainly be highly appreciated by the profession.

The Napoleon mine is west of the west belt of the Mariposa slates. The country rock in close proximity to the mine consists of silicious igneous rocks, meta-rhyolite and meta-trachyte. The character of the ore varies; it is partly rather silicious, partly massive pyrite; it is most probably an irregular replacement of a basic rock, as some serpentine is found in the inclusions of country rock in the ore; occasionally nodules of segregated quartz are found in the massive pyrite.

The Pool mine is about six miles west of Angels, on the road to Milton, on the east slope of Bear mountain. According to the Jackson folio, this mine is in the eastern belt of the Mariposa slates; the country rock is a chlorite schist; a boss of serpentine cuts through one side of the shaft. Probably the ore forms in an altered basic intrusion, which does not show at the surface sufficiently to be marked on the map. The ore forms in the lamination planes of the schist, occasionally in seams several inches wide, so close together as to form orebodies.

Mariposa County.

The Green Mountain mine is in the southwestern corner of Mariposa county, in a belt of mica-schist 600 to 1000 ft. wide, between a mass of granite lying to the east and south, and a silicious eruptive rock, with a glassy groundmass and comparatively few crystals. The orebody is a more or less irregular mass of mineralized schist, the mineralization following roughly the laminations of the schist. It is probable that the eruptive rock may have had some influence on the mineralization of the schist. As the orebodies do not reach the granite contact it may be assumed that the fracturing of the schist, to which the orebodies are due, was caused by intrusions into the schist. In this particular this mine differs from the Pocahontas mine, a few miles to the northwest, where the ore forms on and close to the contact of the schist and the granite.[5] The mineralization of the schist has been accompanied by the formation of a large amount of amphibole. The ore consists of massive pyrrhotite, containing very little silica and some copper, gold, and silver; also of more or less altered schist, carrying disseminated iron and copper pyrite, in fine particles or streaks.

The Lone Tree mine is a mile northwest of the Green mountain. The sulphide orebody is overlaid by talcose schist, an alteration of the mica-schist. The ore is a pyrite with associated chalcopyrite.

Madera County.

In the extreme western portion of this county, close to a large mass of granite which extends from southeast of Daulton northward to the Green Mountain mine in Mariposa county, a number of copper deposits are found. They are in mica-schist, and form a belt that runs apparently parallel, and at a distance of one-half to one mile west of the contact of the schist and the granite. It appears as if in this vicinity the mineralization has spread over a number of parallel fracture-zones, each of rather limited width. The character of the ore differs in the various deposits: At the Ne Plus Ultra mine (two miles south of Daulton) the sulphide ore is principally a pyrrhotite; in the three parallel veins of the Jessie Bell mine, near Daulton, the mineralization has taken place along seams following the planes of schistosity of the schist, the ore is formed by seams of chalcopyrite, or chalcocite and chalcopyrite, resembling the process of mineralization at Copperopolis. Adjoining the Jessie Bell to the north, a vein of quartz, running conformably to the schist, is opened up to some extent; in this quartz are found leaflets of metallic copper and nests of mica and graphite.

Fresno County.

The copper belt continues into Fresno county. Close to the eastern rim of the Great Valley, the Fresno and the Painter mine are situated in this belt. The Fresno mine is about 15 miles east of north from Fresno. The country rock is hornblende-schist. The mine is not far from the contact of the schist and the granite; the schist overlies the granite. The ore is a cupriferous pyrrhotite, with some pyrite, forming a number of elongated lenses. About two miles northwest of the Fresno mine, is the Painter, in massive mica-schist, surrounded by granite. A dike of diorite cuts through the mica-schist, close to the vein,

[5] J. A. Reid, MINING AND SCIENTIFIC PRESS, March 21, 1908, page 392.

in the trend of the laminations of the schist.

About 18 to 25 miles, a little to the north of east from Fresno, is a district containing numerous copper deposits, of which the Copper King mine is the principal. The prominent rock formation is a hornblende-biotite granite, wherein are found lenses or bodies of altered igneous rocks, varying in composition, including extensive bodies of serpentine, which represent either more basic portions of the original rocks or a local serpentinization. Although my geological study of this district was not detailed, my impression is that this schist formation constitutes a belt, having a general northwest direction, inclosed in the granite; it runs, as far as observed by me, from Mill creek, a southern tributary of Kings river, northward across Trimmer springs to near Sentinel on Big Dry creek. All the copper deposits are in the schist, some on the contact with the granite.

The Copper King orebody lies in the schist, adjoining a more or less altered diabase. It forms one much elongated lens, cut off at the southeastern end by a north and south dike, and feathering out at the northwest end. The sulphide ore is a replacement, and the varieties of the ore probably represent varieties in the original rock: some of the ore contains blotches of zinc-blende, closely imitating a porphyritic diorite with feldspar phenocrysts, which is found fresh in the vicinity of the mine. Other specimens show phenocrysts of quartz, which have been replaced pseudomorphically by pyrite.

Conclusions.

The copper deposits in the western foothills of the Sierra Nevada are principally located in the 'greenstone' series, occasionally in the Mariposa slates, and then generally in their metamorphosed facies, and exceptionally in the Calaveras formation. In places they are close to, and sometimes at the contact with, the granodiorite and granite. There is reason to believe that they are genetically related to the late Jurassic or early Cretaceous eruptions. Before we can, however, advance a well conceived hypothesis on this question, a more careful study would have to be made of the copper deposits scattered to the east of the copper belt. It is a mistaken idea that the copper deposits on the western slope of the Sierra Nevada are limited to this belt: scattered copper deposits are found all along this slope, although possibly under existing topographical conditions, commercially useless.

The maximum pressure on the granite masonry of the towers of the Brooklyn bridge is about 400 lb. per sq. in. In the Washington monument, Washington, D. C., the normal pressure on the lower joint of the walls of the shaft is 280 lb. per sq. in., and the maximum pressure brought upon any joint under the action of the wind is 350 lb. per square inch.

Iron consumption in the United States in April was 979,000 tons, as contrasted with 2,093,000 tons in the corresponding month of 1907. The average shrinkage in consumption for the last four months has been 52% as compared with the same period a year ago.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—BLASTING WITH DYNAMITE.

A miner who was familiar with the ordinary dangers of blasting with dynamite, was not entitled to recover for injuries occasionad by a delayed explosion, where he determined for himself the length of time he should wait, and where he knew there was a possibility that a charge which had not exploded might explode later.

Wilson *v.* Atlantic Crushed Coke Co., (Pa.) 68 Atlant. 671, Jan., '08.

DEATH OF MINER—PROOF OF NEGLIGENCE.

Where a miner was killed while descending a man-way in a mine, the proof was held sufficient to show that the miner was killed by falling rock due to the negligence of the mine owner in failing to properly timber up the way. It was also held that the evidence was sufficient to justify a finding of freedom from contributory negligence.

Hotchkiss Mt. & Reduction Co. *v.* Bruner, (Colo.) 94 Pac. 33, March, '08.

LOCATION OF CLAIM—AMENDMENT OF NOTICE.

A person in possession of a mining claim, who has done the actual physical work required by the statute, where such work exists as evidence of the possession, and where there are no intervening rights, such person may amend his location, and thereby perfect his entry; and his right cannot then be defeated by one who had made no peaceful entry and possession of the land, and who had done no work thereon.

Ware *v.* White, (Ark.) 108 Southwest. 831, Jan., '08.

LOCATION OF MINING CLAIMS—MARKINGS.

The mere disconnected markings of a mining claim, unaccompanied by work, and without actual possession, are held insufficient to constitute a location.

Ware *v.* White, (Ark.) 108 Southwest. 831, Jan., '08.

MINING PARTNERSHIP.

By an agreement between the owner of a mine and another person, the latter was to furnish the necessary labor in operating the mine, and each was to receive one-half the profits, to be divided after they had reached a certain amount, and the latter person was then to receive a half interest in the mine; or such person was entitled to purchase a half interest of the mine at any time for a certain sum. Such second person then entered into an agreement with other persons by which they contributed various amounts to work the mine, and for the purpose of securing the option, and such second person agreed to convey to those so contributing, of the interest he was to receive, amounts in proportion to their contribution. In a controversy among such persons, it was held that the agreement created the relation of partners as between such second person and others contributing.

Bentley *v.* Brossard, (Utah) 94 Pac. 736, March, '08.

LODE AND PLACER LOCATIONS.

According to the United States Statutes, where the lode or vein within the limits of a placer location is excepted from the patent to the placer claim, such lode or vein and 25 ft. on either side thereof is open to exploitation and location by any citizen of the United States, for which purpose he is entitled to enter into possession.

Noyes *v.* Clifford, (Mont.) 94 Pac. 842, March, '08.

POSSESSION OF MINING CLAIM—PRESUMPTION.

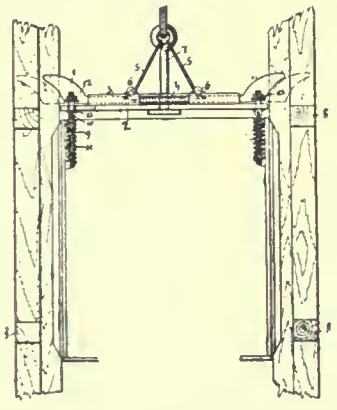
The mere possession and improvement, in the absence of other things, will give no value to a mining claim; their only force is to raise a prima facie presumption that the possession is rightful, and thus prevent the land being subject to original location as wild and unimproved land.

Ware *v.* White, (Ark.) 108 Southwest. 831, Jan., '08.

MINING AND METALLURGICAL PATENTS.

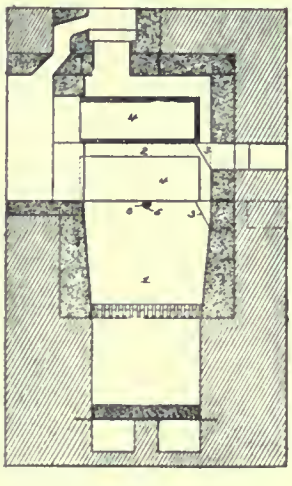
Specially Reported for the MINING AND SCIENTIFIC PRESS.

MINER'S CAGE.—No. 887,193. Heinrich Heiling, Daldrup, near Dülmen, Germany.

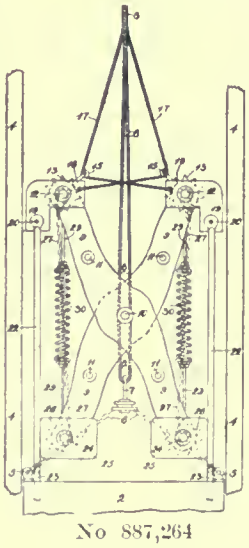


A safety device for miners' cages and lifts, comprising in combination with the shaft, the hoisting-rope, the drawing-rod, and the cage; a separate top for said cage, strong springs arranged to suspend said cage from said top, spring influenced bars connected to said rod and movably arranged on said top and adapted to be pressed outward within the reach of the transverse beams of said shaft upon the breaking of said hoisting-rope and having such a shape as to stand oblique to said transverse beams, and provided on the oblique sides with roughened surfaces, means to fix said top firmly to said cage when raising dead load, and means to prevent said bars entirely from moving when raising dead load, all for the purpose set forth.

ASSAY-FURNACE.—No. 887,057. Lafayette Baudendistle, Denver, Colorado.



No. 887,057



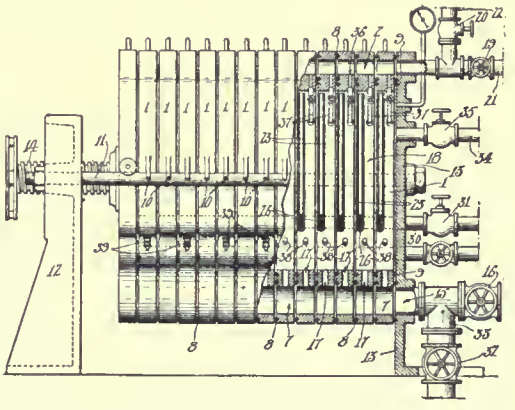
No 887,264

In an assay-furnace, the combination with means for supporting the ends of a muffle, of a pipe constituting a support for the muffle between the ends thereof, a supply pipe for a cooling medium communicating with the supporting pipe, a controlling valve in the supply pipe, and a check valve in the supply pipe between the controlling valve and the supporting pipe.

SAFETY BRAKE MECHANISM FOR MINE CAGES, SKIPS, AND LIFTS.—No. 887,264. Alfred M. Newman, Johannesburg, Transvaal.

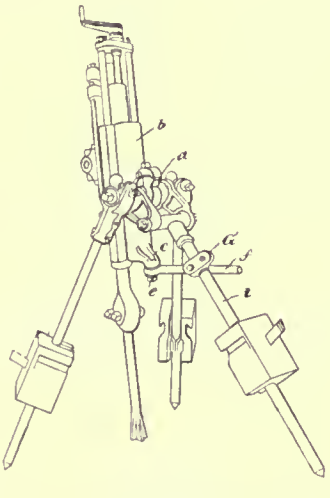
In apparatus of the nature specified, the combination with the vehicle of two pairs of levers pivoted at the centre and located at opposite sides of the vehicle, shafts carried by and between the extremities of said two pairs of levers, wheels mounted on said shafts, timbers with which the wheels are adapted to contact to arrest the movement of the vehicle on the breakage of the suspension gear, means for expanding said levers to cause the wheels to engage the timbers, and means operated by the wheels to further expand the levers to bring the vehicle to rest.

FILTER.—No. 887,285. Ernest J. Sweetland, Goldfield, Nevada.



In a filter, a series of frames each having a hollow ear at the bottom, means for holding the frames closely together, thereby forming a chamber with a conduit along the bottom, each ear having a port extending to the chamber, the frames also having hollow ears on either side of the bottom ears forming side conduits, filtering means in the chamber, and nozzles connected with said side conduits for discharging into the chamber at a point below the filtering means.

DRILL-SUPPORT.—No. 887,301. Albert Ball, Claremont, New Hampshire.



The combination of supporting legs and means to connect them at their upper ends, a drilling machine supported on said legs, a bracket projecting from the drilling machine and terminating in a spherical tip, a stay-rod having a cup-shaped end applied to said spherical tip and adjustably connected therewith, and a clamping device applied to one of the legs and performing the double function of fixing the adjustment of the stay-rod within the clamp and fixing itself in an adjusted position on the leg.

PROCESS OF TREATING IRON.—No. 886,668. Pearce Wilks, Dartmouth, Nova Scotia, Canada.

The herein described process of purifying or decarburizing iron, which consists in subjecting a pile of sheet, or scrap, iron to a welding heat in contact with slaked lime for causing a combination of the surface impurities of the iron with such lime, maintaining the iron at a welding heat in contact with slaked lime for a sufficient period to cause a progressive diffusion of the impurities from the interior of the iron to the previously purified surface thereof and a subsequent combination of the impurities with the lime in contact with the surface of the iron, and working the purified pile at a welding temperature to expel the lime and the impurities combined therewith.

MINE REPORTS.

GUANAJUATO CONSOLIDATED MINING & MILLING, GUANAJUATO, MEXICO.

The handsome report of the Guanajuato Consolidated Mining & Milling Co. for the fiscal year ending December 31, 1907, is no more elegant in the matter of paper, typography, and superb half-tone illustration, than excellent in the logical and explicit statement of fact touching every detail of mining and milling operations and financial results. It is essentially logical to begin a mining report with a statement of the year's development work in the mine, which is the index to the future. This statement is tabulated in such minute detail that, in conjunction with the elaborate maps accompanying the report, any stockholder may accurately determine the status of the mine. It appears that the total advance during the year has been 5271 ft. of work, including 475 ft. of shaft-sinking. The greater amount of work was done on level 6, amounting to 3255 ft., and 571 ft. of advance was made on level 7, these lower levels being almost wholly new. The outcome has been to reveal ore reported as 'blocked out,' classified by shoots, as follows: No. 1, level 5, 5250 cu. ft., or 350 tons for every foot of development work; San Francisco, between levels 6 and 7, 143,333 tons; San Faustino, 151,333 tons. Ore developed is reported in tons only when the blocks have been completely explored by drifts, cross-cuts, and raises. A new double-drum hoist and two 60-hp. motors for operating it have been installed at the Soledad station of the tunnel level, a new hoist has been installed on the San Francisco shaft on level 6 to facilitate the development of the ore-shoot below that level. A Gould triplex electric station-pump, as well as the Knowles electric station-pump, were equipped with new phosphor-bronze acid-proof fittings. A new Ingersoll-Sargeant air-compressor with a capacity of 1200 cu. ft. of free air per minute was also installed, with the necessary connections. Aside from these, very little additional equipment was provided. The supply of labor was scarce throughout the year, necessitating the introduction of mechanical appliances to a greater extent than formerly. The prevailing wage scale for the more common classes of labor was: helpers on machine drills, ₱2; hand-drillers, ₱1.05; shovelers, 75cv.; hoist-men, ₱1.50 to ₱2; skip-men, ₱1.25; timber-men, ₱1.25; track-men, ₱1.50; tool-sharpeners on machine-steel, ₱3, and on hand-steel, ₱2.50; trammers, ₱1; time-keepers, ₱1.50; watchmen, ₱1; and motormen, ₱1.75. Machine-drillers using hammer-drills were paid 15cv. per metre, and piston machine-drillers received ₱3 per day. The total ore mined during the year was 111,504 tons, of which 83,451 tons was delivered to the mill-bins. The ore was extremely uniform in grade, averaging 12.945 oz. silver and 0.057 oz. gold per ton, having a gross value of ₱1,606,776. The mill, consisting of 80 stamps, was operated 338 days and a fraction, the time-losses being due to power-off, 10 days; repairs, 11 days; and a strike, 6 days. The average stamp-duty was 3.13 tons per day through a 50-mesh screen. Concentrate produced was 2154 tons, equivalent to 2.54% of the total ore milled, having a gross value of ₱787,858, representing an extraction of 48.61% of the silver and 45.81% of the gold, or 48.21% of the gross value of the ore milled. There was cyanided 83,160 tons of concentrate sand-tailing, divided into 474 charges of 40,846 dry tons each, assaying 6.5 oz. silver and 0.059 oz. gold, with ₱9.62 per ton. The cyanide sand-tailing contained 2.099 oz. silver and 0.006 oz. gold, or ₱2.98 per ton. The slime-plant treated 42,620 dry tons, in charges of 34 dry tons each, assaying 7.026 oz. silver and 0.029 oz. gold, giving a value of ₱10.31 per ton. The slime-tailing assayed 2.154 oz. silver per ton and 0.006 oz. gold, or ₱2.94 per ton. The extractions were, therefore, from the sand, 68.97%, and from the slime 70.37%. It is to be noted that the actual bullion recovery was ₱582,607, which exceeded the theoretically indicated recovery to the extent of ₱2135.

The costs per ton at the mine were as follows: labor, ₱2.5321; patio (dump), 15.19cv.; crusher-plant, 23.42cv.; hacienda (including the items of dynamo-tenders, mechanics, blacksmiths, peones (common labor), electricians, carpenters, and firemen), 13.35cv.; general, 9.59cv. From the mine costs the following items of greater interest may be selected, namely, powder, fuse, and caps, 27.98cv.; electric power, 14.33cv.; air-drills and repairs, 5.98cv.; drill-steel, 2.04cv.; air-hose and connections, 0.25cv.; lumber, 0.59cv.; skips, 0.4cv.; and candles, 10.55cv. The grand total mine-expense was ₱4.4263 per ton. Development cost ₱1.0953 per ton. Total costs of crushing and concentrating were ₱1.2353 per ton, of which the chief items were: labor, 39.85cv.; supplies, 16.84cv.; electric power, 54cv.; assaying, 2.76cv.; and general expense, 3.29cv. The stamp-milling cost 14.82cv., the Wilfley tables 16.29cv., and the vanners 0.38cv. per ton of total ore milled. Failure to credit each kind of concentrator with its corresponding duty prevents a comparison of costs per ton of material treated on each. The cyanidation cost ₱3.66 per ton, of which slime-tank operation cost ₱1.08, and the sand-tanks 93.99cv., and the precipitation 41.22cv. The total cost was therefore ₱10.41 per ton of ore treated. The company is capitalized at $3,000,000, and has outstanding 7% debenture bonds amounting to $140,900, and 6% mortgage bonds of $42,400. The cash available is: 7% bond redemption reserve sinking-fund, $8588; surplus, $15,000, and undivided profit, $5609. A unique feature of the report, which is worthy of general imitation by mine managers, is a chart constructed on the same plan as a mill flow-sheet, showing distribution of staff and labor, thus accounting for every employee and revealing graphically his post of duty. To this is joined a tabular summary of the labor distribution, from which it appears that there were employed per day 31 Americans and 961 Mexicans.

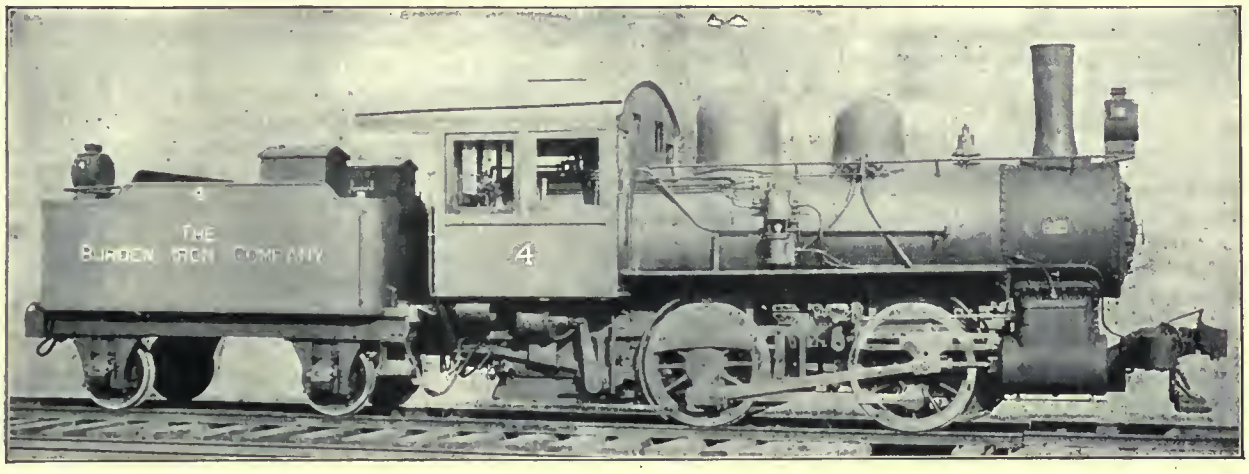
THE EXPLORATION CO., LTD., LONDON.

The report of the Exploration Co., Ltd., for the year 1907 shows a debit of £32,458, from which is to be deducted £19,882 brought forward from the previous year, leaving a debit balance to profit and loss account of £12,576. The directors offer as apology for this unfavorable outcome, which is accompanied by a shrinkage of the market prices of its investments amounting to £158,418, the "serious and universal depression in securities of every class during the past twelve months, and to losses sustained on realization of various investments. The market depression affected the value of practically all the company's investments, and especially of the shares in copper-producing companies referred to in the previous report, which were responsible for £85,000 of the above depreciation." The investments referred to were made on the basis of a selling price for copper of about £65 per ton, so that the directors look for resumption of profits from this source. The statement is made that the development of the Maravillas copper mine, in South America, did not give the hoped-for results, and the option has been abandoned after an expenditure of £18,428. The company has been disposing of its South African mining shares, but retains its Mexican interests. The Somera Gold Mining Co., Ltd., has been absorbed on terms satisfactory to both parties. The El Oro., Ltd., has proved of great value. The reduction works were completed in October last, and a first dividend may be expected during the first half of 1908. The Tomboy Gold Mines Co., Ltd., continues to earn large profits, and the developments are eminently satisfactory.

Criticism of the disastrous results of the year's operation has been severe, and charges of incompetency were freely brought against the directorate. Notwithstanding this, the old board was re-elected, and is given a chance to redeem the financial position of the company. The El Oro mine has just arrived at the productive stage, and recent developments are showing large bodies of high-grade ore in depth. Another large Mexican gold property will also be added to the list of investments within a short time. The sale of shares in the Transvaal mines is explained on the basis of doubt as to the treatment foreign companies may receive under the self-governing colony as constituted through the efforts of the late Sir Henry Campbell-Bannerman.

SWITCHING LOCOMOTIVE.

The accompany illustration shows the general appearance and design of a four-wheel switching locomotive with four-wheel tender recently built by the American Locomotive Co., of New York, for the Burden Iron Co. This engine is intended for switching service in the yards of the above mentioned manufacturing company, and represents the builders' standard 16 by 24-in. cylinder four-wheel locomotive with separate tender. Within the past few years the American Locomotive Co. has been standardizing its small locomotive designs, and as will be seen from this design,



has been particularly well worked out for the service for which the engine is intended, and is an excellent one for service where light rails, poor road-bed, and short curves are among the conditions.

The cylinders are 16 in. diam. by 24-in. stroke, and are actuated by Richardson balanced slide-valves. The total weight in working order, all of which is of course on the driving wheels, is 85,000 lb. With a boiler-pressure of 180 lb. and driving-wheels 50 in. diam., this engine has a maximum tractive power of 18,800 lb., which, using the usual figures for resistance on the level and 20 lb. per ton for 1% grade for grade resistance, gives this engine a net hauling capacity, exclusive of locomotive and tender, on a 1% grade of 640 tons, and on a 2% grade of 330 tons. With 18,800 lb. of tractive power it will be noticed that the weight on drivers gives a factor of adhesion of 4.52, which is an excellent figure for an engine of this type, designed for switching or industrial purposes. With a wheel-base of 84 in., this engine will easily negotiate a curve of 65 ft. radius.

A careful study of the principal dimensions will show that particular attention has been paid to securing the proper ratios between heating surface and grate-areas, and heating surface and cylinder-volume. With 85,000 lb. on drivers, the engine has a load per wheel of 21,250 lb., which can easily be carried on a 60-lb. rail. In this design the tender, which is of the U shape flat top type, has a water capacity of 2500 gal. and a fuel capacity of 3 tons of coal. The tender-frame is built of steel channels.

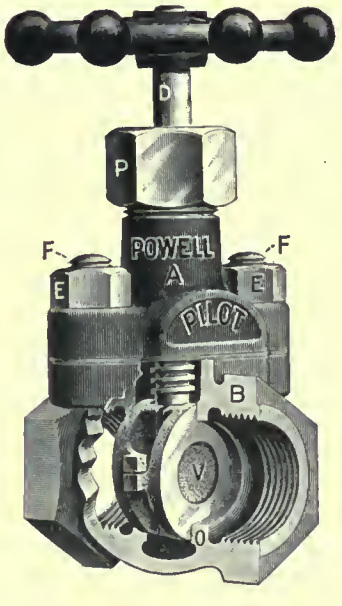
A wood-burning stack could be easily applied to this engine and would make the design (with weight all carried on drivers, large factor of adhesion, short driving-wheel base and ample water and fuel carrying capacity) very well adapted for logging service and similar work near mines.

PORTABLE ASSAY OUTFIT.

A compact, easily transportable apparatus for making assays of the common metals which shall have a close approximation to the accuracy of refined analytical methods, has long been needed. Prospectors have struggled with blow-pipe outfits, which are useful when minerals of any size can be obtained, but which are valueless for the determination of the quantities of gold, silver, copper, or lead in ores which would be of commercial importance, and engineers have resorted to home-made kits of limited applicability for carrying into the field to guide them in reconnaissance, which have only partly fulfilled their purpose. Recognizing the need of a portable assay laboratory which would yield actual quantitative results, L. M. Pritchard has arranged a series of simple methods, with appropriate reagents and apparatus, in compact form, which it is claimed will enable extremely accurate analyses to be made of ores of gold, silver, copper, and lead, by persons of ordinary intelligence who can follow the simple instructions given. Mr. Pritchard claims accuracy which will check up closely with the work of chemists in well-equipped laboratories, except when the metallic content in the ore is very large. A trace of gold is indicated as certainly as by the fire assay. These outfits are put up by the Prospectors Supply Co. of Los Angeles in different sizes, the largest, equipped for 200 assays of the four metals named, weighing only 24 pounds.

GATE-VALVE.

The Pilot iron body gate-valve is another addition to the already long list of steam specialties manufactured by the Wm. Powell Co., of Cincinnati. The illustration shows a strong compactly built valve with every detail carefully worked out. The iron body is built for service and is de-



signed with heavy lugs on either side of the neck, carrying stud-bolts F; the bonnet cap A has corresponding lugs drilled to template, which insures a perfect fit and constant alignment at all times, and also allows the bonnet to be replaced without unusual care after being taken apart for inspection or repairs. Two semi-finished hexagon nuts E, large enough to admit wrenching down hard, with a joint of the best packing material between the faces of bonnet and body, make an absolutely tight joint for all pressures

up to 100 lb. Note the large brass packing nut, P, affording plenty of room for packing material to prevent leakage around the stem. The brass stem, D, and bonnet are chased and cut to a true Acme thread of unusual length, the best for wear. The length of thread keeps the stem in a true axial position at all times, whether open or closed. The knobby hand-wheel gives a firm grip, even though the hands may be oily. The discs are double, not a single wedge, with ball-and-socket back, making them adjustable. They are hung in recesses to the collar on the bottom of the stem. The discs, working in a tapering seat, expand or collapse in opening or closing, making a valve that will close down tight without straining or open easily, no matter what the conditions may be. This all-iron Pilot gate-valve will be found especially valuable in controlling ammonia, cyanide solutions, acids, and all other liquids or gases that attack brass.

BOOKS RECEIVED.

MINES AND MINERALS OF THE BRITISH EMPIRE. By Ralph G. Stokes. 8vo., 396 pp. Ill. Index. Edward Arnold, London. 1908. Price $4.20. This is an attractive and well printed volume by a young journalist who has traveled in the different mining regions under the British flag. He is favorably known as a contributor to the technical press. A large amount of useful information is collected within the space of this book, and it is offered in a presentable manner. The illustrations are on glazed paper and are excellent. The reading matter is on dull paper and is well printed. The author, besides giving a handy book of reference, has discussed many economic problems in an interesting way, so that the book will commend itself to the mining engineer desirous of keeping himself well informed.

A DICTIONARY OF SPANISH AND SPANISH-AMERICAN MINING AND METALLURGICAL TERMS. By Edward Halse. 8vo., pp. 380. Chas. Griffin & Co., London. 1908. This is a handy dictionary, of convenient size, clearly printed in bold type, on good paper. It is the most complete collection of Spanish words and phrases that has yet been prepared with definitions in English, and the system of cross-references makes it easy to trace out the significance of technical or colloquial mining phrases from any word serving as a key. For example, 'a coil of fuse' can be found whether called a *rueda de mecha*, or *rollo de guia*, by reference to either of the four nouns, any one of which will lead to all the others. Similarly the various expressions for 'open-cut work' are traceable, whether the key-word used as the starting point be *tajo*, *cielo*, *cantera*, or *labor*. It will be an invaluable assistant for anyone engaged in Spanish-American mining or metallurgical operations. For sale by the MINING AND SCIENTIFIC PRESS.

DECORATION OF METAL, WOOD, GLASS, ETC. By H. C. Standage. Pp. 228; index. John Wiley & Sons, New York. 1908. Price $2. For sale by the MINING AND SCIENTIFIC PRESS.

This is not an ordinary book of household recipes for renovation, but a brief clear statement of how the finishing and decorating of metal, wood, and so forth, are done by the skilled artisan, with formulas for all substances employed. It would be useful to the master-workman as a handy reference book, to manufacturers, and to those who have a passion for keeping things spick and span. As an example of the field covered, a few items will suffice, such as bronzing, metallic coatings, dips, stains, enamels, and vitrous glazes, preparation of luminous paper, etching metals, lacquers and japanning, and polishing wood.

THE ARCHITECT AND BUILDER'S POCKET-BOOK. By Frank E. Kidder. 15th ed., pp. 1703. Ill. John Wiley & Sons, New York. 1908. Price $5. For sale by the MINING AND SCIENTIFIC PRESS.

The chief improvements in the new edition of this well known and invaluable hand-book consist in a new chapter on re-enforced concrete by Rudolph P. Miller, the editor, who has succeeded the late Frank E. Kidder. The chapter on fire-proofing is more than half new, and is thoroughly in accord with most recent practice. Mr. Miller speaks with authority on this subject, having been chief engineer of the Department of Buildings in New York City for the past five years. The regulations which he was instrumental in drafting for that department have constituted the basis of those adopted by the large cities throughout the United States.

PUBLICATIONS RECEIVED.

We have received the following Bulletins from the U. S. Geological Survey: No. 327, 'Geological Reconnaissance in the Matanuska and Talkeetna Basins, Alaska,' by Sidney Paige and Adolph Knopf; No. 329, on 'Structural Materials Testing Laboratories at St. Louis, Mo.,' by R. L. Humphrey; No. 331, 'Portland Cement Mortars and their Constituent Materials,' by R. L. Humphrey and William Jordan, Jr.; No. 333, 'Coal Mine Accidents, their Causes and Prevention,' by Clarence Hall and W. O. Snelling; No. 334, 'The Burning of Coal Without Smoke in Boiler Plants,' by D. T. Randall; No. 336, 'Washing and Coking, Tests of Coal, and Cupola Tests of Coke,' by Richard Moldenke, A. W. Belden, and G. R. Delamater; No. 339, 'The Purchase of Coal under Government and Commercial Specifications on the Basis of its Heating Value,' by D. T. Randall.

COMMERCIAL PARAGRAPHS.

THE WOOD DRILL WORKS, Paterson, N. J., have issued a circular describing their rock-drill.

THE MINNEAPOLIS STEEL & MACHINERY CO. has moved its San Francisco office to room 716 Chronicle Bdg.

THE RAND DRILL CO. have recently put on the market a new type of pneumatic hammer, which is well adapted for welding stamp-stems.

THE PELTON WATER WHEEL CO., San Francisco and New York, has issued bulletin No. 4, describing Pelton water-wheels and accessories.

THE MCLAUGHLIN MFG. CO. announces the sale of two of the new McLaughlin traction engines for use in the haulage of heavy lumber and mining timbers.

CHALMERS & WILLIAMS, Chicago, have lately closed a contract with the Croesus Gold & Copper Mining Co., Hailey, Idaho, for a complete Huntington mill plant.

SULLIVAN MACHINERY CO. has issued catalogue No. 61, describing stone-channeling machines, and bulletin No. 58-D, on Corliss straight-line air-compressors.

ARTHUR KOPPEL CO. have recently received an order from the City of St. Louis for 18 special, standard gauge, 80,000-lb. capacity garbage cars, and another large order for standard 12-yd. cars.

THE GENERAL ENGINEERING CO., Salt Lake, Utah, have issued a pamphlet which they call 'Ore Testing Bulletin,' describing their laboratory and methods for the predetermination of ore processes. Several pages of tables and useful data are included.

THE LUNKENHEIMER CO., Cincinnati, Ohio, has recently issued its 1908 catalogue, which it is willing to send, free of charge, to anyone interested. The book comprises 500 pages descriptive of its line of engineering specialties, and 60 pages of tables and useful data.

D. C. DEMAREST, lately associated in the management of the Angels Iron Works at Stockton, Cal., has retired from active association in this work and opened engineering offices in the Hooker & Lent Bdg., 503 Market St., San Francisco. Mr. Demarest will give his entire time to the design and sale of mining machinery.

BYRON JACKSON IRON WORKS announce the shipping of a complete patent suction gold dredge to the Kievicz Mining Co., at Fairbanks, Alaska. This dredge, which is similar in design to the Dubois dredges now operating on the Sacramento and American rivers in California, has been particularly built for the conditions to be found on the Tanana river, where it will be operated.

Editorial.

PAYMENT FOR BULLION deposited at the United States mints and assay offices in the Western States will not be made in Eastern exchange after June 10. The practice of issuing New York drafts for bullion deposits has resulted, since the Spanish war, in accumulating in the San Francisco mint $300,000,000, of which $240,000,000 is gold. The only outlet which the Western mint has for its specie is through the demand for coin or bars by depositors, and through the payment of warrants issued by the Treasury Department.

REPORTS of the discovery of gold in the Anadir district of Siberia are appearing in the daily press and will revive the hopes of profitable mining on the Asiatic side of Bering Sea. Several expeditions have failed to find rich gravel across the way from Nome and the Russian officials have made the most of concessions from which they expected to gain. News of discovery should be accepted with caution. We shall be glad to find the information true.

AT SEATTLE, the Northwest Mining Men's Convention has been in session, under the presidency of Mr. A. W. McIntire, formerly Governor of Colorado. Resolutions were passed endorsing the creation of a Bureau of Mines in the Department of the Interior, the preservation of natural resources, the revision of the mining laws, and the prevention of fraud in mining, but the most interesting resolution was that protesting against the oppressive rates on traffic to and from Alaska and the ports of the Northwest.

PENNY POSTAGE between Great Britain and America will be in effect next October. This is a most important reduction in the cost of communication by mail and will stimulate business across the Atlantic. It is well known that this much desired reform would have been effected long ago save for the opposition from Canada, where penny postage has been in force, to the advantage of commercial relations with the mother country. Eventually we hope to have the same minimum rate throughout the Postal Union.

THE YAQUI rebellion, in Sonora, appears not to be ended yet. With characteristic indifference to truth, the newspapers announce one day that hostilities have ceased, only to narrow it down the next to negotiations with a single chief. It turns out that the news published in our regular Mexican correspondence on May 30 gave the facts five days before the same information reached the daily press through the medium of its telegraphic service. It is to be hoped that the Indians will make peace, however,

without suffering the hopeless struggle to be prolonged. This war was incited by graft, it has been perpetuated for the sake of graft, and a rich country has been kept from benefiting either the native or the foreigner. With the advent of the railroad the pressure of civilization is rendering it impossible for either the grafters or the Yaquis to continue the state of affairs that has existed for so many years, and if the Indians do not lay down their arms the troops will probably at last make an effective campaign against them. The region involved is rich in gold, silver, and copper. At Fundicion, on the edge of the district, the smelter of the Douglas Copper Company was blown in two weeks ago.

Valuation of Mining Shares.

WHAT mining school will be first to recognize that applied science must be economic science and that it will never be allowed to cumber the affairs of men by being uneconomic? Observe that economic science is not the science of economics. There is such a thing as applied science of economics also, and this needs to be added to economic applied science in the training of technical students to fit them for the proper exercise of their duty as leaders of a great part of the industrial movement of the age. The old struggle and mutual contempt of 'town and gown' still survives in a singularly large degree. The man on the street has not fully made up his mind to accept the college graduate as a safe person to be trusted with control of the engines of finance, and in spite of much cringing to capital and frank avowal of money-making purposes, the collegian, even of the technical sort, has not quite overcome the ancient academic arrogance which finds in commercialism a taint and a blemish. The question which the faculty of the technical school needs to put to itself is what special equipment it is giving its students to grapple firmly with the problems of plain business involved in the successful application of scientific knowledge. How may a student expect to understand the complicated problems of exchange, banking, and finance, if he is not instructed in them? The commercial school is assuming an ever greater importance in the preparation of young people for a business career. The day of apprenticeships has nearly passed. The trade unions have frankly abolished the system, and the commercial world is brushing it away. Men engaged in strenuous work under modern conditions have no time to be school-masters, and are impatient of the blunderings of inexperience. Time was when the mine accounts were a matter of ill assorted jottings in the manager's pocket memorandum book. The exaggeration of this statement would not have seemed so striking twenty years ago as it appears today. But the mining graduate goes forth to deal with the complications of mining finance with no more preparation than was given the student then, except in so far as every keen intellect gains some comprehension of the conditions of his era by absorption.

In our Discussion department last week Mr. Newton B. Knox gave an illuminating explanation of certain principles involved in estimating the true value of a mine. In this issue he is followed by an interesting letter from Mr. C. W. Purington. How many technical students are able to swing free from a theoretic scheme and apply sound principles of accounting to the solution of a special problem when a client demands guidance in the financial plans which the conditions of the enterprise impose upon an honest and conservative board of directors? It is time that technical schools should recognize the need of establishing chairs of financing and accounting to better equip young men to meet the responsibilities of practical life, and to win success without struggling against the disadvantages of that sort of apprenticeship which in all branches of human endeavor is becoming obsolete, and hence more difficult to acquire after entering upon an active career in the field.

Manufacturing Good Times.

PRESS dispatches declare with a big flourish that the financial stringency is being waived by the railroads. In exact quotation: "The official announcement that the Illinois Central has decided to ignore what remains of the financial depression is likely to set the pace for other large systems which have been withholding similar orders until the conditions are fully normal." This is all with reference to the action of the Illinois Central Railroad in placing an order for 52,000 tons of steel rails, to cost $1,456,000. The joke is that Mr. Harriman's Illinois Central Railroad places its splendid order with Mr. Harriman's Tennessee Coal & Iron Company. This is heralded to a credulous public as an example of courage and magnanimity in a corporation determined to conquer hard times by stimulating industry for the general good. We have no quarrel with a man who uses such prosperity as his railroad may possess to save depreciation and loss in his steel plant. Idle machinery deteriorates: closed doors drive away skilled labor: each enterprise has its separate responsibilities and obligations. Hence the one-man influence exerts itself in the direction of self-preservation when it employs one enterprise to feed another: in so doing the welfare of many is served, and a restoration of normal financial conditions may thereby be promoted. But it is pitiful to note how the Associated Press counts upon the ignorance, or forgetfulness, or mock-earnestness of the public. The purpose of such misleading statements as the one quoted above is plain enough. The great corporate interests work in pleasant accord, and the press is harmonized with the traffic and commodity monopolies, so that news is constantly colored to lead the people to conclude what it is desired that they should believe. It is worth while now and then to be reminded of bondage lest we forget entirely what our condition is. In spite of ourselves, this continual soaking in lies, in misrepresentations of truth, and in distortions of fact, results in absorption of false impressions, and our judgment becomes clouded when we try our hardest to see straight and true. We all desire a return of prosperity, but we do not wish a see-saw of confidence, so that when depleted stocks compel resumption of large production in various branches of industry, the general

public will have been further impoverished by the relentless spoliation of market manipulators. Speculation thrives upon credulity, not upon knowledge, and the men who take up the shout that the big corporations are 'waiving' the financial depression are those who lay wisdom and caution aside, and swell a 'wave' of dollars to break on the beach of Wall Street for the benefit of the piearoons infesting that dangerous coast.

Devious Ways.

THE steam-heated imagination of Mr. Lawson will be working over-time in the near future, for he has been given an option on the Guggenheim holdings of stock in the Nevada Consolidated, Cumberland & Ely, Steptoe Valley, Utah Copper, and other corporations working copper mines in Nevada and Utah. This option has five months to run, so that the bombardment of the public intelligence by the Boston filibuster is expected to begin at any moment. In a recent issue of our New York contemporary there is a reference to the Copper Mines Company, a consolidation with $60,000,000 capital that is to absorb the enterprises above mentioned, but *The Engineering and Mining Journal* is misinformed: the scheme for merging the Nevada Consolidated with the Cumberland & Ely, and the further merging of these properties with those of the Utah Copper, and the Steptoe Valley companies, has been set aside, probably because it was known that the minority interests would fight vigorously and effectively against a watering process that would have turned a copper vintage of high quality into the *vin ordinaire* of a diluted stock merger. The Guggenheims own a dominant interest in a number of copper companies, operating mines, mills, and smelters in Utah and Nevada; they own only a bare majority, or a working majority with financial friends, in the best of these enterprises, while owning nearly all the stock of the poorer undertakings; therefore a consolidation would have impaired the individual value of the separate properties and enhanced the price of the poorer at the expense of the better stocks. There has been talk of some such Wall Street prestidigitation for many months; the formation of a holding company to own the shares of the Guggenheims and their associates is the alternative finally chosen. It is a clever move. Obviously, the effect will be to lessen public interest in the shares of the separate companies, and hence to depreciate them, by focussing attention on the consolidation of majority interests, the shares of which will have greater stability than those of any single enterprise. The gravity of wealth is at least as remarkable as the falling of the apple that caught Newton's eye. And apart from this aspect of the case, the episode has a deeper significance. It is another example of the manner in which obligations, responsibilities, and laws can be evaded by the up-to-date financier. A corporation owning the stock-holdings of a group of men is a legal entity as devoid of character as a meteorite, as amenable to public opinion as a horned toad. It is simply a beautiful device for juggling the stock-market. We regret—and this is no figure of speech—that the Guggenheims, so honorably and for so long prominent in the business of mining and smelting, should have turned their clever hands from industrial operations of a highly useful kind to stock manipulation of an utterly pernicious character. If anyone can lead them down a steep place into the sea, it is Lawson; whatever few millions they may win by the medium of his buffoonery and bunco-steering, they will lose in other ways. Already their credit has suffered by the Yukon fiasco; the stock the public foolishly bought at 8 and 9 dollars is selling for less than $4, and Lawson's flamboyant rot was unable to create a market for a much over-capitalized, though meritorious, mining scheme. Even should the Guggenheims make two or three millions by the further assistance of Lawson, their financial credit will suffer by more than twice the amount filched from the pockets of the public by means of the frothy advertisements of a pseudo-reformer and irresponsible pamphleteer.

Mexican Banking.

THE Mexican banking law has just been modified in many important respects. That which especially challenges attention is the great increase in capital required for banks of issue, which has been raised from one hundred thousand to a minimum of one million pesos. It is clear that Sr. Limantour, the minister of finance to whom these reforms are chiefly due, intends that there shall be no departure from the purpose of the old law. The Mexican banking system was based essentially on the Scotch principle of strong central institutions, serving the needs of smaller centres through branches and agencies. Industrial development in Mexico during the recent years of extraordinary business activity tended to stimulate the establishment of many banks. The law as now altered puts a check on reckless incorporation of banks and regulates the financial currents within the Republic. A community may subscribe capital to a *sucursal* or branch of some large bank, thus in a measure making it a local enterprise, for the branches operate on capital of their own, but they are tied to and controlled in their policy by the central institution. This makes for solidity and safety. The Mexican banking system has long been superior to our own; now it advances a step further on the road of conservatism, while we are inflicted with a patchwork bill, rushed through Congress in the last hours of the session against the protests of our leading bankers. Thus our system is complicated so that it is not understood by the people, and is viewed with suspicion by all classes save the few in whose interest it was constructed. Mexico feels the need of building up her strength, and she has a statesman in Diaz, and a financier in Limantour, to do it. We are strong, and rather inclined to a happy-go-lucky kind of legislation, confident that we can survive our errors. The statesman and the financier of the highest ability do not control national legislation. The inevitable result is to add to our difficulties in time of business depression through mistrust in the mechanism of our institutions of credit and exchange.

Personal.

JAMES W. NEILL is in town.

J. H. CURLE is in Tierra del Fuego.

F. J. H. MERRILL has gone to New York.

HARRY S. DERBY has returned to Colombia.

MARK B. KERR has gone from Bodie to Tonopah.

LIONEL LINDSAY has returned to London from Spain.

GAYLORD WILTSHIRE has returned from British Guiana.

ROBERT SCHORR arrived in New York from Europe on May 21.

RALPH NICHOLS recently visited the copper country of Michigan.

W. H. SHOCKLEY is here, on his return from southern California.

E. H. MESSITER has returned from British Columbia to New York.

EDMUND JUESSEN was in San Francisco, on his way to Portland, Oregon.

BENJ. B. THAYER has been elected a director of the Amalgamated Copper Company.

C. L. DIGNOWITY, of Reno, Nevada, has been spending a few days in San Francisco.

C. L. WHITTLE, of Boston, is examining mines at Rollin, in Siskiyou county, California.

F. H. MORLEY, of Denver, has gone to Chihuahua, Mexico, and will be there for two months.

ALFRED FRANK has been appointed manager for the Davis-Daly Estates Copper Co., at Butte.

F. F. SHARPLESS, of the Consolidated Mines Selection Co., has returned to New York from Mexico.

PHILIP READE BRADLEY has sailed for British Guiana, where he is manager of the Peters mine.

EDGAR E. WARREN has left London for Spain, where he is about to open up mines on his own account.

T. A. RICKARD will visit the principal goldfields of Alaska, sailing from Seattle about the middle of June.

T. H. LEGGETT and FREDERICK HELLMANN will make an examination of the copper mines at Ely, Nevada.

J. E. SPURR and J. H. FARRELL are making a geological survey of the Camp Bird mine, at Ouray, Colorado.

F. W. BRADLEY has gone from Wardner, Idaho, to the Alaska-Treadwell mine, of which he is consulting engineer.

FRANK H. MASON has resigned as manager for the Johnston-Graham Mining Co., and is now at Paso Robles taking a rest.

JOSEPH P. GAZZAM, who has been supervising the erection of a dredge in Mariposa county, California, has returned to St. Louis.

D. T. WILLIAMS, for many years chemist to Elliotts Metal Co., South Wales, has opened an office and laboratory at 42 Finsbury Square, London.

WILLIAM A. HEYWOOD has opened an office at 4 Broad St. Place, London. He has gone to Chile, as consulting metallurgist to the Copiapo Copper Company.

OBITUARY.

J. F. O'GORMAN died in Mexico on May 17. He came originally from Dublin, and had resided in all parts of the world, representing various mining companies. For the last three years he had been installing an elaborate water-power plant near Choix, Sinaloa, in connection with a smelter project.

LEMUEL U. COLBATH, aged 76, died at Salt Lake on May 26. The deceased was one of the veteran mining men of the West, having operated on the Mother Lode of California in the early days; he later went to the Comstock, and thence to Utah, where he became actively identified with the development and management of the Ontario Silver mine, at Park City.

General Mining News.

ARIZONA.

COCHISE COUNTY.

Clark & Scanlon have sold a group of five claims in the Copper Creek mining district, 75 miles north of Benson, to Manager Sibley of the Copper Creek Co. It is claimed that there is a vein 10 ft. wide which assays 14% copper, 27 oz. silver, and $5 gold.——The 80-stamp mill at the Pierce mine is running only half-time.

MARICOPA COUNTY.

The Relief mine has closed down for two weeks on account of shortage of water.——The Monarch M. & S. Co.'s new mill, nine miles east of Wickenburg, is to start soon. The mill has a capacity of 50 tons, and replaces the 35-ton plant destroyed by fire last May. When the mill is in operation the force in the mine will be increased.

MOHAVE COUNTY.

A company of Butte men has taken a bond on the Emerson mine, at Chloride.——J. J. Connolley and others have taken a lease on the Little Flores mine, at Cerbat, and are to unwater the property and begin work at once.——The Utah-Arizona Gold Mining Co. has purchased the 5-stamp mill of the old Suncloud Mining Co., at Signal, and will move it to the property of the company in the Weaver district.——The Elkhart mine, at Chloride, has been sold to a company of Eastern men, who will develop and work it at once.

SANTA CRUZ COUNTY.

(Special Correspondence).—The Saleros Mines Co., operating in the Tyndall district, is making extensive preparations for active mining. The ground has been thoroughly prospected with a diamond drill. A wagon road from Patagonia, a distance of 12 miles, is now under construction. The company will sink a 500-ft. shaft in the Darwin claim and drive an adit in the Eureka. The ore bears silver and copper.——It is reported that the Gringo mine, in the Tyndall district, will install new and heavier machinery and will double the capacity of the present 10-stamp mill. The shaft is now 500 ft. deep.

Patagonia, June 1.

CALIFORNIA.

INYO COUNTY.

The two-compartment shaft of the Bishop Creek Gold Co. has reached a depth of 50 ft. A new hoist and a Leyner drill have been installed. The diamond drill which is working in the canyon recently struck at 150 ft. two feet of sulphide ore which assays $34 per ton. This hole is over 200 ft. from the first, in which similar ore was found.——The Southern Belle mill is running on ore from the Bullion, which is being taken out by the tramway in the New York adit. Eight miners are stoping in the 325-ft. level of the Bullion.——A contract has been let to advance the Index adit, near Pine Mtn., 350 ft. farther. It is expected that three veins will be cut before the Bull Domingo is reached.

NEVADA COUNTY.

(Special Correspondence).—Another bed of rich gravel has been encountered on the Weare claim, near Banner Mtn. Blair & Tregonning of this city have decided to purchase the property and operate it on an extensive scale. ——A promising gravel channel has been struck by Joseph Weaver on the Fowler ranch, on the south slope of Banner Mtn.——The company owning the Conlan mine has decided to resume operations. Sufficient money has been raised by the stockholders to carry on the necessary developments. ——A force of men has been put to work in the lower levels of the New York-Grass Valley mine. From $1500 to $2000 will be expended monthly in developments.——Work has been resumed at the Midas mine, after a brief shut-down. ——Nevada City parties have obtained a bond on the Mt. George claims, at Indian Flat, and will sink the shaft 150 ft. Three shifts will be employed.——A cave occurred in the lower level of the Yuba mine last week. A miner was seriously injured. Little damage resulted to the mine.—— The Champion mines at Nevada City have suspended operations for an indefinite period. Considerable ore is blocked out in the lower levels but it proved of too low a grade to mine profitably. The group was under option to an English syndicate and its closing means a heavy blow to the prosperity of the town.

Grass Valley, June 1.

SHASTA COUNTY.

The Balaklava mine has resumed, employing 30 men.—— The Mountain Copper Co. is again doing its own diamond-drilling, the recent contract with the Arizona Diamond Drill Co. having expired. The work now being done is confined to the Hornet claim.——The Gladstone mine, on French gulch, has been capitalized by its owners for the purpose of raising funds for extensive development and equipment.

SIERRA COUNTY.

A company of Colorado men has taken a bond on the old Colombo mine and will open it at once. They have also a 30-day working option on the Eley mill, in Jim Crow canyon, and have a force of men at work preparatory to a test run.——Dolan & Bell have resumed work at the Gum Boot mine, in Slug canyon.

On the Sierras.

SISKIYOU COUNTY.

Welch & Sons have started their hydraulic elevator, on Grouse creek, and are using three giants.——The old mill at the Mattern mine has been purchased by Varley & Fowler, who have moved it to their Quartz Valley property.—— The Elk Creek Mining Co., on Canal gulch near Hawkinsville, made a clean-up of $1500 after a 20-day run with a 2-stamp mill.——The Wood Rat bar, on the north side of Klamath river, between Ash and Humbug creeks, has been bonded to a company of Cleveland (Ohio) capitalists who will begin operations at once.

TUOLUMNE COUNTY.

The Tuolumne Water & Power Co. is extending a transmission line from Jamestown to supply power for the Omega mine.——A shaft is being sunk on the Brunson ranch, near Keystone. The incline shaft of the Joe Hooker, on the Calder ranch, has been cleared and will be deepened. ——The Philadelphia is building a ditch to carry water to its gravel property above Columbia.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A bonanza strike has been made in the Capital mines. In starting a new raise between the fourth and fifth raises on the west drift of the Aetna vein, 15 ft. of ore has been exposed, which assays as high as 30 oz. gold per ton. Running through the main body are a number of streaks of rich ore containing free

gold. This is one of the most important strikes ever made in Clear Creek county, for the reason that it occurs at a vertical depth of 1700 ft. from the surface.——The Chilean mills, which broke down last week, have been repaired and the concentrating plant is again running night and day. On an average 125 tons of mill dirt is being treated daily.——Work will be in full swing at the Hall adit within two weeks. Arrangements are being made for the installation of a modern compressor plant, and the machinery will be ordered at an early date. It will also be necessary to put in 2500 ft. of new track. A number of Pittsburg capitalists have become interested in the company, and funds will be forthcoming for finishing all proposed work. B. J. O'Connell has been appointed manager.——Shipments have been made during the last week from the Sidney adit, East Argentine. Lessees at work on the blind vein which was cut 2125 ft. from the entrance, are breaking a heavy tonnage of high-grade ore. Carlson & Co. are working a body of ore that is from 18 in. to 3 ft. wide and average returns are received at the rate of $70 per ton in gold, silver, and lead. Killin & Co., leasing to the east, have an 8-in. streak of ore that is worth 2 oz. gold, 35 oz. silver, with small quantities of lead and iron.——The Almaden property is shipping high-grade ore that yields more than $90 per ton in silver and lead. These holdings have been undergoing development for the last two years, but it has only been during the last few weeks that large and rich pockets of mineral have been found. The mine was a heavy producer a number of years ago.——A 20-year lease on the John M. Osborne placer, near lower Fall river, has been granted by the Pittsburg Con. M. & M. Co. to the Dover & Brighton M. Co. The latter secures the use of all water-rights, with the exception of the water needed for the operation of the Brighton mines. It is understood that by the terms of the contract the Dover & Brighton Co. will increase the capacity of its mill from 50 tons to 300, and that all ores from the Brighton mines will be treated at a cost of $1.25 per ton. J. C. Sturdevant of Idaho Springs is general manager for both companies.——The Duncan group of claims, on Columbian Mtn., has been secured by the Golden Glory T. M. Co. The mine is at present developed by an adit level 250 ft. long, at the face of which a winze was sunk 70 ft. The property is equipped with engine, boiler, hoist, etc., and work has been started.——B. J. O'Connell, leasing on the Mendota below the Victoria adit level, is sending out an average of 100 tons of lead-zinc ore monthly. The product is being separated at the Mendota mill, which at the present time is running on custom ores.——The richest ore mined in many years in the Leavenworth Mtn. district is being extracted from the Ocean Wave level of the Colorado Central. Stoping is in progress upon a streak of mineral that measures from 18 in. to 3 ft. wide, and returns from 200 to 700 oz. silver per ton are being received. F. A. Maxwell is operating this property under bond and lease, and as the bond falls due July 1, 1908, an effort is being made to get out as heavy a production as possible.——A number of lessees are at work on the Kirtley, on Leavenworth Mtn. This property has remained practically in idleness for over twenty years, but as the vein runs parallel with the Colorado Central, and has produced some exceptionally high-grade ore, the outlook is favorable. McClusky & Co. are carrying a stope from the main level and have encountered a streak of quartz mixed with ore that is from 6 to 10 in. wide.——The workings of the Wide West have been placed in good condition and now cross-cutting will be started to get under the shoot from which a heavy production was made a few years ago. L. Baccheiri is operating under lease.——The Drummond group of five claims, four of which are patented, situated on Columbian Mtn., has been taken under bond and lease by the Golden Glory T. M. Co. The bond calls for $25,000, runs for five years, with royalty of 15% on smelting and 10% on concentrating ore, with all royalties applying on the purchase price. In the bottom of the winze, down 90 ft., there is exposed a 14-in. streak of silver-lead ore that mills $44 per ton. Operations were started this week.——A new strike has been made on the Sporting Times, Alpine Mtn. In extending the drift on the Moore vein a streak of solid smelting ore has been uncovered that is from 16 to 20 in. wide, and assays 1½ oz. gold, 15 oz. silver, and 55% lead.——L. B. Banks & Co. have taken a lease on the Coulter group of four claims, situated on Leavenworth Mtn. The adit, in 700 ft., is being advanced, and the Lone Tree vein will be reached within the next 50 ft.——The Homestake M. & M. Co., operating a group of claims on Lincoln Mtn., will resume work in a few days. This company is composed of a group of Georgetown business men, and no stock was ever placed upon the market. The adit, in 150 ft., is to be driven forward under contract, and the first vein will be reached within 20 ft.——E. E. Grubb has started work upon the Dewey property, Columbian Mtn. The adit is being driven ahead and a small streak of decomposed sulphide ore is exposed which assays 150 oz. silver per ton.——Work is to be resumed in a few days upon the Annie May group of claims, Columbian Mtn. The adit, now in 150 ft., is to be advanced. In the breast of the adit there is exposed a 6-in. streak of brown sulphide ore that mills as high as 300 oz. silver per ton. The vein runs parallel with the Stemwinder.——The Pelican mill will be started some time next week. The motors are now being connected and the mill-bins are filled. This plant has just been remodeled, the capacity having been increased from 125 tons to 250 per day. The aerial tramway running from the Seven-Thirty dumps, is practically completed.——In extending the Kalamazoo adit on the Snowdrift a streak of heavy lead ore was recently encountered on the hanging-wall. Some ore is being mined, but it is the intention of the management to continue driving ahead to reach the Snowdrift vein, which lies about 100 ft. distant.——Nels Williams has resumed work upon the Comet Extension, situated on Griffith Mtn. This property was formerly a good producer, but has been in idleness for a number of years.——It is understood that the Comet will soon pass over to the Capital M. & T. Co., a deal having been under way for several weeks. The Comet is an extension of the Aetna, which is yielding such large and rich bodies of high-grade ore at the present time.——The Old Missouri mine, on Seaton Mtn., has been taken under bond and lease by Jos. Boyd of Idaho Springs. The work of cleaning out the shaft and various levels will be started at once, and as soon as completed the shaft will be sunk 100 ft. deeper.——Work is to be resumed on the Kinda mine, on Bellevue Mtn. If the Lucania adit is driven ahead, the Kinda vein will be reached within 200 ft. It is reported that the owners of the Lucania now have the matter of resumption under consideration.——The raise being carried from the fifth to the fourth level on the Little Mattie mine has been completed and a free circulation of air obtained. The lessees are carrying a stope on a streak of ore that is from 10 to 20 in. wide and from which average mill runs of more than 80 oz. silver per ton are being received.

Georgetown, June 1.

LAKE COUNTY.

The machinery which was formerly used on the old Graham property has been moved to the Catawba, which is under lease to Alex. Harvey and associates.——The large extension to the trestle from the Yak tunnel has now been in use for several weeks, and the electric trains have been successfully running over it. There is sufficient space between the ends of the old and new trestles to take care of the waste that will be hauled from the mine for many years.——Iron shipments have been started from the Shamus O'Brien on Yankee hill, which is under lease to Andrew Clooney and asociates. The work on this property is being carried on near the surface.——John Shimmins, who is leasing on the Star of the West, on Iron hill, will start shipments this week. Mr. Shimmins has had a force of men at work on this property for several months, and just recently encountered a body of ore from which he will send about 25 tons per day to the smelters. The material contains iron, but also carries a percentage of lead.

SAN JUAN COUNTY.

Work on the excavation for the Kittimac mill, near Mid-

dleton, has been suspended temporarily, pending some alterations in the plans.——The California Mountain Mining Co. will start operations next week at its property two miles east of Animas Forks.——A rich strike is reported from the property of the Fleece Mining Co., in Picayune gulch.——The litigation between the Tom Moore and the Minnie Gulch Mining companies has been amicably settled. All the suits have been dismissed and the receiver has been discharged.

IDAHO.

LATAH COUNTY.

(Special Correspondence).—The Latah Copper Mining Co. has ordered a boiler, hoist, engine, and compressor, and will sink a winze below the present adit level.——All machinery for the reduction plant of the Mountain Gulch Gold Mining Co. is on the ground and ready to be set up. The ore is a friable quartz-gold.——Active work has commenced on the Sampson group, owned by Portland capitalists.——The Gold Nugget Co. has begun development on its group of claims adjoining the Mountain Gulch.——At the Mizpah the raise from No. 2 adit has been driven 90 ft. This will connect with the shaft, and as soon as the work is completed shipments will begin. A railway is promised by the Idaho, Washington & Montana Railway Co.——A shaft is being sunk on the West Mizpah Co.'s property. The ore of both properties consists of copper oxides in the upper workings.

Moscow, June 1.

IDAHO COUNTY.

(Special Correspondence).—Nine feet of lead ore is exposed in the bottom of the shaft being sunk on the vein in the Granite & Allie property, on Granite creek, near Burke. The shaft is down about 120 ft. and will be sunk to a depth of 200 ft. before driving is begun. Assays give returns of $67 per ton in lead, silver, and gold.——The Champion Copper is driving both ways on the foot-wall of the vein recently cross-cut. About 20 ft. of this work has been done and the ore in the face of the drift averages about 6% copper.——Development work on the famous Pilot mine at Murray is to resume June 1. A cross-cut adit which was started last fall will be continued 200 ft. toward the vein. The Pilot is the mine from which the richest gold ore ever found in this district was taken in the summer of 1906. Samples of this ore assayed as high as $30,000 per ton.——The new stamp-mill being put up at the Shamrock property, near Thompson, is rapidly nearing completion, and will be in operation within the next month. There is a large quantity of gold ore ready for the start.——Work has commenced on the driving of the 4122-ft. tunnel on the Copper King property, near Mullan. The tunnel will give a depth of more than 800 ft. below the lowest of the present workings, but it is estimated that, owing to the dip of the orebody, the vein will be encountered at a distance of about 3200 ft.——An accidental discovery at the property of the North Fork Mining Co. near Wardner shows that for some time past the men have been working in a black carbonate ore. A sample brought up to Wallace gave assays of $100 in copper, $90 gold, and 30 oz. silver per ton.

Wallace, June 1.

A carload of machinery for the Frisco Mines Co. has been shipped from Paterson, N. J. The car contains a boiler, engine, compressor, electric generator, several machine drills, a saw-mill, and complete accessories. An additional order has been placed for a 5 stamp mill.——The Idlewild group of claims, at the head of Campbell gulch, has been sold to J. D. Wooden, and work has been resumed.——W. H. Kirk has resumed work on his Saradoc group, on Blowout mountain.

SHOSHONE COUNTY.

(Special Correspondence).—The Hecla mine has resumed operations and about 150 men are now at work. The company will soon be shipping ore, and sinking on the deep-level shaft will also be continued.——The Rex, which closed down a short time ago, will resume work this week, under the management of P. J. Keane, and start sinking from the 300-ft. level to the 650. A force of 18 men will be employed. The level from which ore has recently been taken will be abandoned, and the mill will not start again until large reserves are developed.——The Charles Dickens mine, on Moon creek, will be running the newly completed concentrator in another fortnight. Reserves of ore have been opened for a continuous run.——J. L. Bailor of the Success Mining Co., which recently bought the Monitor mine, near the Montana line, states that the property will be worked this summer, beginning June 15. The Success is under bond to sink 300 ft. and to cross-cut 1500 ft. Work will be done on a winze from the 400 to the 700-ft. level.

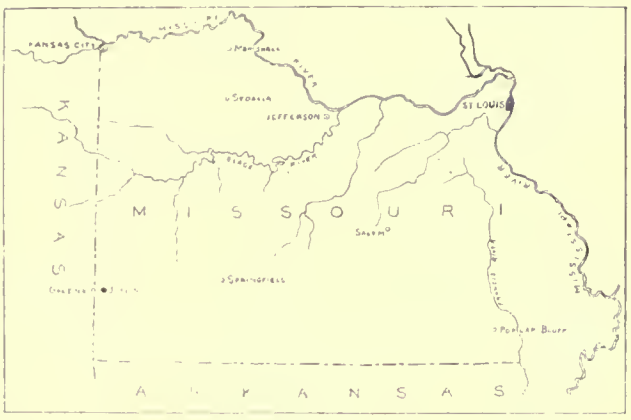
Wardner, June 2.

A. M. Strode has given an option on his interest in the Mineral Farm mining property, near Mullan, to a company of Missoula men. The consideration is not known, but is believed to be $25,000.——Copper glance has been struck in an adit on the Copper Age, adjoining the Monitor mine.——The North Bunker Hill Mining Co. will begin operation on its property next week. A cross-cut adit will be extended 50 ft. farther, where it is expected the orebody which was cut in the shaft will be struck.——A strike of shipping galena has been encountered on the property of the Cedar Creek Mining Co., on Cedar creek, two miles northeast of the Hercules.——A car of ore has been loaded at the Meadow Mountain property, near Saltese, and will be sent to the smelter at once. This is the first car of ore to be sent from the property.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—The Hartford Mining Co. has



Outline Map of Missouri.

completed its new concentrating plant but will not begin operations for some time. The new company is working in virgin territory south of Galena.——A strike has been made on the Charles Rains land, at Happy Hollow, southeast of Galena. A shaft has been sunk to the orebody but driving has been delayed until a pumping plant can be installed.——The rich strike made on the Windle Bros. lot on West Seventh street some time ago has caused many others to lease property in the vicinity and start prospect work. Shellack & McKinney have taken a lease across the street, and will sink a shaft to the same level as the Windle.——The Myrtle Mining Co., at Baxter Springs, has installed a Sullivan air-compressor, a 125-hp. boiler, and a sand-jig. An elevated tramway has also been built, and the plant will soon be running with two shifts.——A new company has taken over the Old Abe mine, and preparations are being made to construct a dam across Crawfish creek, to provide sufficient water to run the mill. The company last week sold 3100 lb. of lead ore.——A rich silicate strike was made near Peoria, on the W. W. Scott land. Four shafts are being sunk on the tract, and one shaft, with two men working, is getting out about two tons per day. A 9-ft. face of the ore has been opened at 35 ft.——A drill strike showing 18 ft. of rich zinc and lead was made on the Little Four lease, north of the shaft. The strike was made by William Earl, and is the fourth drill-hole into the orebody.——A new concentrating plant is being erected south of the Mission mine, on the Big Chief lease. One

shaft is into the ore and some driving has been done.——Iowa and Oklahoma capitalists have purchased the Kramer-Morse mine, at Baxter Springs. The new company has opened up one of the best deposits of ore found in the camp. Drilling has been thoroughly done, and it has proved that an orebody 48 ft. thick underlies a large portion of the lease of 40 acres.——The Good Luck Mining Co. has opened a large body of free zinc ore at the 100-ft. level. A large quantity has been piled on the dump and a concentrating plant will be erected.——The Eastman Land & Investment Co. has overhauled its mill, and has made a number of changes in the concentrating process, which are expected to obtain better results in saving of the fine.

Galena, May 26.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—During the past week there was a decrease in the price of zinc ore and an increase in the price of lead. Zinc brought only $38 per ton, as highest price on an assayed base of $35 per ton of 60% zinc. Lead brought as high as $59 per ton, which was an advance of $1 per ton over the top price of the preceding week. This increase in the price of lead is fortunate for many of the mines in this district, since most of them produce enough lead so that the added income offsets the decline in zinc. The largest producer in the Joplin camp was the Granby M. & S. Co., with 317,820 lb. zinc and 14,670 lb. lead. The total production for the Joplin camp was 1,837,920 lb. zinc and 214,500 lb. lead, with a total value of $37,465. The heaviest producer in the Webb City camp was the Bradford-Kansas City mine, with 541,490 lb. zinc and 58,430 lb. lead. The production for the Webb City camp totaled 2,437,020 lb. zinc and 749,920 lb. lead, with a total value of $63,176.——The Missouri Metals Co. is operating on the Condon land at Chitwood. A drift is being driven at 136 ft. to a drill-hole sunk to that depth which showed good ore. ——A company, composed of Burt Lyon, Leo Yount, A. J. Smith, and F. W. Kelsey, has been organized to develop a 20-acre lease on the Leonard land at Chitwood. Three shafts are already into ore. The new company will further develop the tract by drilling before commencing active operations. After thorough development a modern concentrating plant will be erected.——Several rich strikes have been noted recently in the Chitwood camp, both in new and old workings. Among the more important was the strike made in the Maude L., by Harry Gundling. The Maude L. was a former producer and the strike was made by sinking a winze 20 ft. in the old drift. The shaft has been sunk to an equal depth and the same kind of ore encountered. The Cumberland, an adjoining property, is also being developed by Mr. Gundling.——The new 150-ton mill at the Lounetta mine is now in operation. Drill holes on this land show a rich ore from 68 to 118 ft. Two shafts are down 110 ft. and are connected, but only one drift will be worked for the present.——J. K. Jacobs, of Baxter Springs, has purchased the mine owned by Weir & Co., northeast of Joplin, on Turkey creek. The mine has a shaft in ore at the 100-ft. level, but a great deal of pumping will be done before active operations can be begun. ——Development on the Spencer land in the old Midway camp northeast of Joplin has shown the existence of a large body of ore on the lease of the Kalitan Mining Co. The drill penetrated ore from 12 to 35 ft. thick. Four shafts have been sunk and hoisting machinery installed. ——The Moonshine Hill Mining Co., operating a 36-acre lease on East Seventh street, has struck ore at 85 ft. The orebody is 15 ft. thick. Four shafts are into ore and active operation has begun.——Plans are being perfected for the further development and re-opening of the old Center Creek Mining land, between Webb City and Carterville. This tract produced over $13,000,000, and recent investigation proves that there is still much ore in the upper levels and the lower workings have scarcely been touched. Among the companies operating on the tract is the Good Shepherd Co., which holds a lease on the western line. The company is re-opening some old shafts to reach some uncut ground. A 250-ton mill is being erected.——A rich body of ore has been opened up on the Tom & Jerry lease, northwest of the Good Shepherd. The ore was found at 185 ft. Two shafts have been connected by an incline tramway. A 250-ton mill has recently been completed and is now producing. The ore is of the sheet variety and contains from 3 to 5% zinc-blende, with a small amount of galena.——The Corrie Cole Mining Co. has just re-opened one of the old shafts on the Center Creek Mining Co.'s ground and ore is being taken from both the upper and lower levels. A concentrating plant has been purchased and moved to the property.——Bendelarie & Cook are opening up a sheet ground deposit north of Webb City. Zinc-blende has been found at 215 ft. Two shafts are in ore and driving has been under way for some time. Development has progressed far enough to furnish ore to supply a 250-ton plant which is in course of erection.——A new company has taken over the old Wampler land at Scotland, and is installing pumping machinery. The previous company abandoned the tract on account of high water soon after the completion of two shafts to the 120-ft. level. Galena was penetrated at the 60 and 80-ft. levels, and blende at 120 ft.——The Columbus Mining Co. has erected a tailing mill at Oronogo, on the Old Judge lease, and will treat the tailing from the Old Judge, which assays 3 to 4%, and upon the sludge sand, which contains from 9 to 12% blende.——Development work has been begun on the Wheeler land, at Carthage, just north of Spring River, by Hurley, Fellows & Eckman. A contract has been let for 1200 ft. of drilling. The Garlinger farm, still farther northwest, has been the scene of development work. Two holes penetrated ore at 212 ft. The company will sink nine more holes on the 40-acre lease.——The Davey Crockett Co. is sinking a shaft into a rich body of free ore just east of the Troupe-Mignonette mine. The Troupe Co., on an adjoining tract, is also sinking a shaft to strike a sheet of ore discovered by drilling. The Troupe Co. will soon erect a concentrating plant.——East of Carthage, the Lone Star Mining Co. is developing a 20-ft. face of 10% zinc-blende, found below a zinc silicate deposit. A 200-ton plant is being built.

Joplin, June 1.

MONTANA.

The St. Paul mine, 18 miles south of Libby, has started an adit at the creek level and expects to strike the vein within 40 ft.——The final payment has been made on the Silver Crown property, on Granite creek, 10 miles from Libby. The new owners will put in a compressor and air-drill and push development.——M. S. Lindholm has purchased the property of the Bear Creek Mining Co., on Libby creek, 16 miles from Libby, and is now at work repairing the flume and ditch. Development will be undertaken on a large scale and for that reason Mr. Lindholm does not expect to begin sluicing until next season.

NEVADA.

CHURCHILL COUNTY.

The Fairview Mizpah Co. is putting in a small gasoline engine and a blower to aid in the ventilation of their adit. ——It is reported that a 6-ft. orebody assaying $100 has been uncovered on the Almanto estate.——The new hoist on the Nevada Crown is working, and sinking is in progress on the shaft, which is about 100 ft. deep. The company is also driving an adit to strike the vein at the 250-ft. level.

ESMERALDA COUNTY.

The Round Mountain Mining Co. declared its first dividend last week. The total amount is $32,000, which is at the rate of 4%.——The Nevada Empress Gold Mines Co., which owns a group of claims in the Gold Mountain district, 35 miles south of Goldfield, has purchased a 100-ton mill and expects to have the plant in operation by August 1.——The Loftus Davis Co., which controls the Great Bend, is to sink a 500-ft. two-compartment shaft on that property.——The Victor, one of the properties of the new C. O. D. Consolidated, is the scene of a rich strike by the Victor Leasing Co. Nearly six feet of $50 to $60 ore is

exposed on the 250-ft. level. This strike is encouraging, in that it shows the main ore zone of Goldfield to extend farther southeast than had before been proved.——The work of enlarging and re-timbering the shaft of the Sprague lease, operated by the Puritan Mining Co., has been completed. Lateral work will now be started and two shifts employed.——The mines of Goldfield produced, during the week ending May 29, 1904 tons of ore, valued at $151,360.

HUMBOLDT COUNTY.

The El Rancho Mining Co., at Tip Top, has struck high-grade ore in an adit at a vertical depth of 200 ft., and is now driving another adit at a lower level to determine the extent of the orebody.——The Kindergarten mill and the Mazuma Hills have both started for the first time this week.

LINCOLN COUNTY.

The Nevada Horn Silver Mining Co., at Pioche, has placed an order for a 25-hp. gasoline hoist.——Clayton & Crittenden, who are leasing on the New Year's Gift, have received returns from the car of ore recently sent to the Needles smelter of a little over $43 net per ton.——The Bristol Con. Mining Co., at Pioche, has resumed, employing 15 men. The ore from this property will in future be hauled by wagon to Jack Rabbit, and from there to the freight depot, the Nevada-Utah Co. will handle it on their narrow-gauge system.——The Nevada Central has put on another shift.

LYON COUNTY.

A discovery of rich copper ore was made last week in the Mason Valley mine, at Yerington. A 6-ft. body of cuprite, associated with native copper in the form of fine threads, was uncovered in adit No. 3, at a vertical depth of 350 ft. At the time when the Comstock was in its glory the Mason Valley shipped large quantities of bluestone for the use of the mills along the Carson river.

NYE COUNTY.

The Tonopah-Liberty mine, 25 miles north of Tonopah, is enlarging its mill from 10 to 20 stamps, and is installing a 100-ton Huntington mill.——G. E. Holesworth reports a strike in the Breyfogle, at Manhattan, which he thinks is the Thanksgiving vein. No assays have been made yet, but it is believed to be rich ore.——The Georgia Bullfrog, six miles northeast of Beatty, has uncovered a 6-ft. orebody which assays $272 per ton.——The Security Reduction Co., recently organized to take over the holdings of the New Belmont Amalgamated Co., at Belmont, has placed orders for a 100-ton reduction plant and several mine-pumps.

WHITE PINE COUNTY.

It is reported that the old Egan mine, at Cherry Creek, is to be re-opened.——The Copper Bond Co. is prospecting its ground west of the Veteran mine with a 6-in. churn-drill. They claim to have struck ore containing 18% copper and $2 to $20 gold.——The Ely Bonanza management is unable to lower the water in the shaft and is planning for another method. It is believed the water contains 2% copper.——The Siegel mines, in the eastern part of the county, have been closed down temporarily on account of a reduction of the wage scale. The miners would not submit to a cut of 75c. per day, and hence operations have been suspended until a new force arrives.——The Hunter Con. Mining Co. has been incorporated to take over and develop the mining property a mile north of the Vulcan mine, at Hunter. The new company will at once sink a two-compartment shaft.

OREGON.

The Ashland mine, at Ashland, which has been closed for the last seven years, is to be opened again by a company of Los Angeles men. The mine is flooded below the 500-ft. level. New hoisting and pumping machinery will be installed and a mill erected near the main shaft. The Ashland was a great producer 12 years ago, and has, it is estimated, produced more than a million dollars in gold.——A wagon-road is under construction from the Vesuvius mill, in the Bohemia district, to some mines owned by F. J. Hard. After its completion ores from these mines will be treated at the Vesuvius mill.——A complete water-power electric plant has been shipped to the property of the Washongal Gold & Copper Mining Co., on upper Washongal river. A complete smelting and reduction plant is under construction for the treatment of some high-grade copper ore which the company has blocked out in its mine.——The Greenly Development Co. of New York has purchased a large block of the stock of the Imperial mine, at Cable Cove, and also secured options on all the stock owned by the Detroit syndicate except that of A. H. Sibley. The new company will at once begin development and will drive another adit 300 ft. lower than the Miner. A small force of men is already at work in the drift known as the intermediate level.——It is again rumored that a merger of the Ibex and the Bald Mountain properties has been effected. The Ibex has been proved to be a property of merit, and while the Bald Mountain management has not made public what it really has, it is known that it can be most advantageously worked

Utah.

through the Ibex. The 50-ton mill on the latter is one of the most complete in the district, and would be a profitable adjunct to the Ibex.

UTAH.

BEAVER COUNTY.

The Cupric Mines Co. has been incorporated to work the old Washington property, adjoining the Horn Silver and the Imperial Copper. The new company will not utilize the two inclined shafts now on the property, but have started a new shaft close to the Newhouse or Cactus mine adit.——An air-compressor is now in use at the Hub mine, at Milford, and development is progressing rapidly.

JUAB COUNTY.

The Opex mine, at Mammoth, was closed down last Saturday. The shut-down is only temporary and the development of the mine will probably be taken up again within a week or two. In the meantime some repairs are being made to the boilers.——The shipments from the mines of Tintic for the week ending May 29 were as follows: Centennial-Eureka, 40 carloads; May Day, 4; Eureka Hill, 7; Yankee Con., 2; G. A. Franke (Utah lease), 1; total, 54 carloads.——Work is progressing rapidly in cleaning out the caved portion of the drift between No. 2 and 3 shafts on the 1500-ft. level of the Ontario, at Park City, and it will be only a short time until the draining of the mine is complete and work resumed in the ground that has been flooded for so long.

Special Correspondence.

LONDON.

Montana Mining Co. v. St. Louis Mining & Milling Co.—San Francisco del Oro.—British Broken Hill.—Great Fingall.

Whatever advantage may be urged in favor of the United States apex law, a good many English mining companies have from their experience gained some knowledge of its harassing nature. Perhaps none has suffered so much in this way as the Montana Mining Co., which owns the once famous Drumlummon mine. This company has been the victim of the litigious spirit of its neighbor, the St. Louis Mining & Milling Co., for 15 years, and the dispute is as well known and as insufferably drawn out as Jarndyce *v.* Jarndyce. In the series of actions brought against it, the Montana company has been exceptionally unsuccessful in the lower courts and has won only in the Supreme Court of the United States. Last autumn an action brought by the St. Louis company over the 'Compromise' ground was settled in the Montana company's favor, but the St. Louis company has since applied for leave to amend its pleadings. It has admitted that it has no right to the Compromise ground, but now alleges a claim to the ground known as the Nine Hour Workings, and to one million dollars as the value of the ore taken out since 1893. An injunction has been granted preventing the Montana company from conducting further operations pending a trial. As a matter of fact, the Drumlummon mine is now quite worked out, the old tailing heaps exhausted, and the company intended to shut down entirely this year. The new law-suit will prevent doing this. Though the mine is worked out, the company is considered fair game, for it has £37,000 reserve fund and £33,000 of uncalled capital, besides owning another property at Edgemont, Nevada. I suppose that as long as the Montana company has any resources it will suffer from the persecution of its neighbor. Theoretically the apex law may be perfection, but a good many of us would be quite willing to class the dipping of a vein out of our boundary as one of the risks of mining, along with pinching out in depth, impoverishment of ore-shoots, and similar slices of ill-luck.

In your issue of April 18 one of your correspondents draws attention to a report upon a property, in which the value of the ore is given as the sum of the values of the metallic constituents, quite ignoring the metallurgical question of their extractability. An example of this method of valuing mines was seen in the flotation in London five years ago of the San Francisco del Oro mine near Parral, Chihuahua. The ore deposit contained lead and zinc with a good deal of silver, and some gold and copper. In giving the value of the ore the directors took the average of the assays and added up the metallic constituents. It is hardly matter for wonder that the company has made no profit, and that it now contemplates the raising of further capital, in spite of the fact that the mine has ready for stoping over 300,000 tons, containing 26 oz. silver per ton, 12% lead, and 23% zinc. Shortly after the flotation of the company, some of the shareholders saw the fallacy of the directors' reasoning and declined to pay up all of the calls, preferring to forfeit the £10,000 they had already paid. To show how the directors still cling to the total-value theory, it is only necessary to mention that one of them at a recent meeting of shareholders referred to the gross-metal value of the ore as £8 10s. 0d. per ton at the present low prices of metals, and comparing it to a similarly big gold mine with 2-oz. ore. The policy of the San Francisco del Oro mine has been to ship the most saleable parts of the ore to the smelter, in which way expenses have been met most of the time. The company has always been short of working capital and has therefore been unable to erect concentrators or other plant for the treatment of the ore. At the present time the directors are experimenting with the Sutton-Steele dry concentrators, but their critics are recommending them to try water concentration, on the system adopted at the neighboring Tecolotes mine, where similar ore is found. It is to be hoped that they will be able to raise the necessary money to provide a dressing plant, and to fix upon a suitable process, before all the best ore is picked out. At the present time the shipping-ore is being sorted with particular care, owing to the low price of metals, and much richer ore is now being shipped than was the case a year ago. The rate of shipment is 2000 tons per month. During 1907, the shipments amounted to 7294 tons, which realized £187,736. For a long time, during the last two years, shipments ceased.

The question as to the advisability of closing down a mine partly or totally during periods of low prices of metals is one of the most difficult that is met with by directors and engineers. Some are content to go slow and not hurry their plant, others sort their ores so as to still make a profit, while others take the bold step of closing down altogether, with the intention of not starting again until prices have recovered. It takes a good deal of courage to decide on the last named course, and it is not often that a company with plenty of funds in hand will adopt the plan. It is noteworthy therefore to mention the case of the British Broken Hill mine in New South Wales, which has decided, for the second time in its life, to shut down the mill. The first time was in July 1901, when the mill remained idle until March 1903. In those days lead and silver were very low. When lead recovered to £12, the British Broken Hill was able to resume and work at a profit. A similar crisis occurred at the end of 1907, and the directors decided once more to shut down the mill. It happens that lead is now £13, and the enquiry may be legitimately made as to why operations cannot be conducted while this price rules, although it was worth while re-starting in 1903 with lead at £12. There are several reasons for this. In the first place, the labor association of Australia has fixed wages at a higher rate; secondly, mining operations are conducted at a greater depth and at a farther distance from the mill; and thirdly, the smelters do not now give such good terms, having raised their returning charges recently. The company on December 31 last had a balance in hand of £46,700 and a reserve fund of £10,000. During the stoppage of the mill some development work will be done and the reorganization of the plant completed. Since work re-commenced in 1903, dividends totaling £210,000 have been distributed, and £75,000 spent out of revenue in renewals and additions. During the second half of last year, 68,268 tons of sulphide ore and 929 tons of carbonate ore were raised. The concentrating plant dealt with 69,417 tons assaying 13.9% lead, 14.7% zinc, and 9 oz. silver per ton. The yield was 10,462 tons, assaying 61.7% lead, 8.9% zinc, and 26.8 oz. silver, all of which was shipped to Europe. The recovery was 66.8% of the lead and 44.7% of the silver. The zinc tailing amounting to 48,697 tons, and 10,258 tons of slime was placed on the dump, to be treated hereafter by the Zinc Corporation.

At the Great Fingall mine in West Australia no new discovery has been made during the past year, so that the prediction made by the managers, Bewick, Moreing & Co., a year ago, will probably come true, and the mine may not be expected to last much over a year. Below level 13 there is a large amount of low-grade ore, of which it is difficult to gain a sufficiently exact estimate by sampling to enable the engineers to say whether it will pay or not. During the year 1907, the ore treated in the 100-stamp mill amounted to 261,057 short tons, giving a total yield of 99,215 oz., of which 56,413 oz. was won by amalgamation, 17,580 oz. from concentrate, and the remainder by cyaniding the tailing. The proceeds from the sale of gold were £423,193, and the profit was £174,473. After paying taxes and allowing for depreciation, the net profit was £137,558, out of which £137,500 was distributed as dividend. The adjoining mine, the Kinsella, which in the early Australian days proved unprofitable, has been acquired, primarily with a view to obtaining a water supply. It is intended to pump the mine dry and sample it. It is quite possible that with modern plant and methods of treatment the old mine may now be turned to profit.

MEXICO.

Guanajuato. — New Plant. — Increased Production.—Railroad Facilities. — Zacatecas. — Magistral Smelter. — Guerrero Mill, Pachuca.

Notwithstanding the continued low price of silver, the production of the great old silver camp of Guanajuato seems to have been in no way curtailed, but rather it would appear that production has been increased so that the value of the returns remain somewhere near unchanged. Encouraged by the way in which the Mexican Milling & Transportation Co. has been pushing the work on its Mineral Belt railroad, the entire camp has shown enthusiasm. Some time ago a rich strike of a 4-ft. vein was made in the El Monte de San Nicolas, and another of high-grade ore on the 700-ft. level of the Sirena mine of the Guanajuato Consolidated Mining Co., both of which are adding to the returns of these companies. The Cata and Tepeyac of the Guanajuato Reduction & Mines Co. are also getting into good bodies of ore, and better returns can be looked for in the future from this company. Up to the present time the larger part of the tonnage treated by it has come from the old dumps. The Pinguico and Peregrina, as well as other smaller properties, continue to add their regular quota, and *buscones* are at work all over the camp, so that now the production is well over ₱1,000,000 per month, at a cost of perhaps not more than ₱400,000. The big La Luz properties of Messrs. Bryant and Mellhiney have been floated, and include, in addition to the La Luz group, the Bolañitos and Refugio of the La Luz district, under an organization with $5,000,000 capital, and a 1000-ton reduction plant is being planned by the company. Mr. Geo. W. Bryant has just gone to New York in the interests of this and other Guanajuato properties with which he is connected. The Lewisohns are said to have taken an interest in the San Cayetano, which was bought some time ago from the Mexican Mines Association of London. Chicago capital has become interested with Dwight Furness in the Cabrastante, beyond the Nayal; an electric pump has been put in, the old winze has been unwatered, and an additional 25 metres has been sunk, from which a very good grade of ore is being taken. This gives a material extension to the productive area of the Guanajuato district. El Cubo, another of the outlying properties, which has been a producer for many years, is being thoroughly gone over and rehabilitated. The greater part of this work has been made possible by the introduction of electricity by the Guanajuato Electric Light & Power Co. Additions now being made will give it a distributing power of 20,000 hp. (of which 60% will be used for mining purposes), as against the 4000 hp. brought in five years ago, at which time it was believed the provision made would greatly exceed the demand.

Guanajuato's old records, showing approximately ₱1,000,000,000 of silver produced in the past three and a half centuries, has always seemed like one of the marvels of the mining world, and not a few were skeptical as to their accuracy. But the performances of the present day lend color to the truth of the ancient records, for it is said that now, with something over 600 stamps dropping in Guanajuato, and over 2000 tons being cyanided per day, the camp is producing at a rate three times greater than the old record-rate. This increase in production is due to the new and better methods of mining and treatment, which make possible the handling of the lower-grade ores which formerly could not be touched. Where the old methods entailed an expenditure of from ₱15 to ₱30 for mining and another ₱13 to ₱40 for reduction, with a low extraction, mining and milling today is being done for ₱10 per ton and an extraction of 90% is being obtained. Furthermore, in the old days only the Mother Lode was worked, whereas today all parallel and cross veins are being worked, and from these latter come the gold, which did not attract the old-time miner because of the difficulties of extraction. The completion of the Mineral Belt, connecting all the principal mines and vein-systems with the custom mills, and the entrance of the Mexican Central railroad into Guanajuato proper, is going to give such encouragement to new properties as to cause an even greater production in the coming year.

Incidentally it is pleasant to chronicle the fact that the three Mexicans who so brutally murdered George Rose, the superintendent of the Pinguico mill, in his home in Guanajuato on the night of September 11 of last year, have been sentenced to be shot, and it is not believed that their lawyers will take the trouble to appeal.

The mining conditions in and about Zacatecas are rapidly improving, and it is believed that an additional impetus will be given to the district on the completion of the smelter now being erected by D. H. Norris of the Magistral mine. Though this plant is being built primarily for the Magistral, it will do a custom business as well, and operators will be afforded an opportunity to dispose of their ores to better advantage. The work is in charge of C. A. Haberlein, formerly assistant superintendent for the Torreon Metallurgical Co., at Torreon, Coahuila. The initial plant will only have a capacity of 50 tons, but it will be enlarged to meet increasing demands. The ores of the Magistral run from 8 to 10 oz. silver and 5 to 10% copper. The property is owned by Dudley H. Norris and Charles Gilbert.

Zacatecas, a mining town with a fame once world wide, has during the last twenty years gone from bad to worse,

A Corner of Guanajuato, Mexico.

and the population has dwindled from 80,000 to 30,000 or less. This was in part due to the long drought, from 1888 to 1893, which made the cost of living extremely high. More directly it was due to the mine workings getting down to and below the water-level, thereby adding to the cost of production, at the very time when the great drop in the price of silver took place, in 1893. This necessitated the closing of many properties. Among the few which continued operations was the El Bote, which for the past sixty years has been in bonanza. Last year it was purchased by an English company, and the old amalgamation mill was changed into a cyanide plant with a daily capacity of 250 tons. Encouraged by the results of El Bote, the work of unwatering had been started by the owners of the San Rafael, La Capilla, and the Mala Noche, and new work was undertaken at the Zaragoza and San Roberto, in both of which copper was discovered. Work was also begun on the Veta Grande and the Tajo de Panico, but the low price of copper and silver stopped the greater part of this, and another year will be required to regain the ground lost. Many good properties are in this condition, waiting for money to develop them, among which may be named the San Martin, within the City of Zacatecas, on the northeast side of the Cerro de San Martin, which was closed in 1892 because of trouble from zinc in the ore. Recent experiments with the ore on the old dumps, of which there is about 30,000 tons assaying 10 oz. silver, have shown that it can be successfully treated with cyanide. A company with a capital of $250,000 has been organized to operate this property. A 100-ton water-jacket furnace has been ordered for the Boca del Cobre plant, in the Nieves district. With this property has been incorporated the mines known as

San Nicolas, San Francisco, Santa Rita, and El Rosario, all in a fairly advanced stage of development.

The State of Zacatecas is giving encouragement to work that may be of assistance to the mining districts by granting a concession to Gustav R. Madero for a railroad to run from the station of Camacho, on the Mexican Central, east through the Pica de Teyra district to Mazapil and Concepcion del Oro, where it will make connections with the Coahuila & Zacatecas railroad of the Mazapil Copper Co., running to Saltillo. To another proposed railroad line, having as its object the making of connections between the principal mining camps of the State, there has been granted a subsidy of ₱2000 per kilometre of road built, together with the necessary lands from the State Government. Notwithstanding the bright future which some predict for Zacatecas, the camp which, next to Guanajuato, is making the most rapid strides toward rejuvenation and advancement is Pachuca, in the State of Hidalgo. We have already called attention to the changing of the Hacienda de San Francisco, and several other old patio plants, to the cyanide process, and now we are able to chronicle the completion and placing in operation of the 40-stamp Guerrero mill of the Real del Monte Mining Co., a sub-company of the United States M., S. & R. Co. This is the finishing touch of two years' development and improvement by this corporation. For some time past the Loreto mill, belonging to this company, has been cyaniding the low-grade ores of Real del Monte, and together with the direct shipments to the Aguascalientes smelter the receipts of the Real del Monte Co. has enabled it to declare its first dividend. It is perhaps the largest silver property in Mexico.

BENGUET, P. I.

Transportation Facilities.—Mines on Bued River.—Murphy and Copper King.

Baguio, the capital and central supply point for all the mines of Benguet province, is now within 11 hours of Manila. This has been accomplished by the recent completion of the railroad to Camp One and the establishment of an automobile line by the Government to carry passengers the remaining 20 miles. The two machines just purchased and put into service by the Government make the trip down this tortuous cork-screw road in 70 minutes. There is a drop of 4000 ft., with a maximum grade of 12%. This road, built some years ago to develop the mining interests, cost the Government over two million dollars, and now the skeptics are beginning to realize that the criticized officials were justified in building it.

The clean-up from the Murphy group, six miles south of Baguio on the Bued river, was late going in, due to lack of facilities for retorting. It amounted to 15 oz., valued at a little over $15 per ounce. The plant, which can hardly be called a mill, consists of a puddling box with screens, from which the pulp flows over an amalgam plate 18 in. wide by 8 ft. long. The lumber for this was whip-sawed on the ground. The whole hillside is being quarried and carried by Igorrotes on their backs to the box, where they rub it through the screens with their hands, throwing out the coarse stuff. In this way nearly a ton per day is treated, which furnishes a profit to pay for the mine development work, as only one white man is required. There are eight claims in this group.

The Copper King Mining Co., owning a three-stamp mill, adjoins the Murphy on the north. The vein system here has been opened for more than 2000 ft. from the mill-tunnel, and 1000 ft. lower.

Up the hill from the Copper King, H. P. Whitmarsh has the East Extension of this vein on his Philip claim. There is also on this claim another vein averaging 9 to 14 ft. in width and assays $10. This ore contains no copper, but much manganese and calcite. It is opened up by 120 ft. of adit and cross-cuts.

Across the mountain from the Philip, the Copper King vein is again found on the Ascencion group, owned by Calvin Hoar and others. This group consists of 10 claims, on which there are two main veins opened up by 976 ft. of adits and cross-cuts, scattered over the different claims. These workings show the veins to cross four claims. The Copper King lode, still dipping toward the north, shows its characteristic chalcopyrite ore in quartz, while the other vein is associated with manganese and quartz stringers, dipping 70° toward the south. On the Igorrot claim a 70-ft. adit cuts the south lode, which is then driven on for over 160 ft., where it averages 3 ft. wide, with 400 ft. of 'backs.' On the other side of a main ridge a 150-ft. adit cuts this lode, which is then driven on for 140 ft. toward the other workings, which are at a level 60 ft. lower. When the necessary raises are completed there will then be blocked out enough ore to warrant a mill. This ground requires very little timbering. On the Ascencion claim 190 ft. of driving shows the other lode to average 3 ft. of ore. It is also opened by small surface cuts and by an adit lower down on the other side of the mountain, on the Ascencion Annex claim, where it averages 4 ft. wide. On the Emerald claim this lode is opened by a 96-ft. adit. Work is progressing rapidly, and a mill will soon be provided if the present development discloses the ore now indicated. A superintendent's house and quarters for the laborers have lately been erected.

JOHANNESBURG, TRANSVAAL.

Labor Problems.—York Mine.—Condition of New Unified and Nigel.

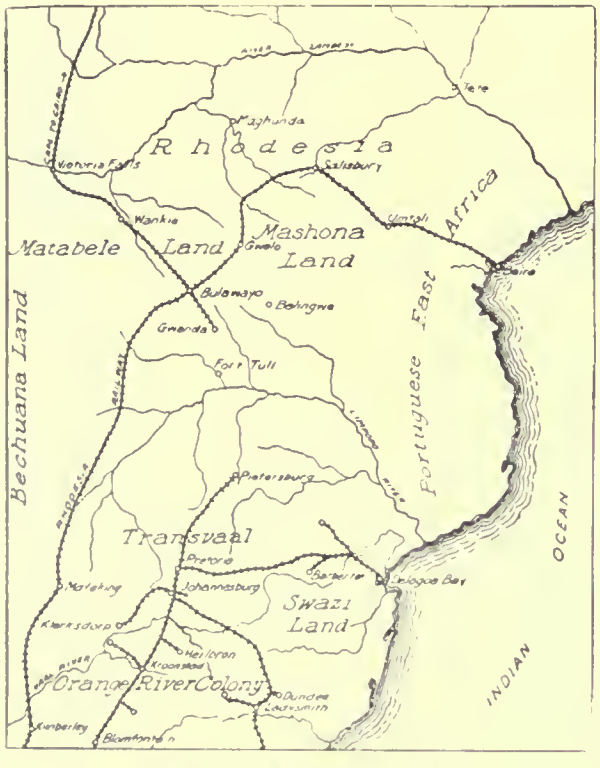
The problem of white labor on the Rand is the topic that is receiving the most attention at the present time. Although there have been some disappointments, the Government seems determined to solve the problem of the unemployed by finding work for the whites in the mines or municipalities. One of the leading daily papers is championing the cause of white labor, and in almost every edition gives the latest information concerning the white men who are doing rough laboring work in several of the mines. The experiment being tried at the Consolidated Main Reef mine is being watched with interest. Here they are replacing the Kaffirs by white men in the handling of the tailing. The white men take the work on contract at 4½d. per ton, and it is hoped they can earn between 5 and 6s. per day. So far the reports from the mine are not very favorable, but people still hope that the experiment will be a success. If found to be as cheap to employ whites in handling the residues from the cyanide works as to use Kaffirs, and if all the mines agree to do this class of work with white men, then the problem of the unemployed will be easily solved.

Another interesting experiment is being tried on the Ferreirra Deep mine. The Gordon drill people have taken a contract to break rock with their small machines, on the understanding that only white men be employed. It is thought that the higher intelligence of the white man will enable him to do this work cheaper with this machine than with Kaffirs. The terms given to the white men are such that an intelligent energetic man will be able to earn from 10 to 13s. per shift. The experiment has not been running long enough to know whether it will be a success or not.

On the York mine, in Krugersdorp, the departure made by Abe Bailey is turning out well. Instead of employing Kaffirs at the sorting tables, as is universal on the Rand, youngsters from 12 years and upward are put on to pick out the waste rock. They are earning from £3 to £4 per month, and this money is a great help to the indigent Dutch families to which they belong. The policy on the York seems to be to employ a white youth in preference to a Kaffir wherever it is economically possible to do so. The white sorters are working just as cheaply as the Kaffirs, and are doing better work. It is to be hoped that the other mines will follow the example set at the York mine, and employ white youngsters in the sorting department. One of the problems of the Rand is to find employment for the white youths who are growing up in our midst. The sorting houses will be a good school for them, where they will learn lessons of industry, and when they grow older they may go into the mine. A great obstacle to the success of the white labor is the opposition of the skilled artisan. Naturally the doctrine of the '£1 per shift' is jealously

guarded. They are against any scheme that tends to bring down wages. They readily see that if a large number of whites are taken on at a low wage, these workers will be only too pleased later on to do the skilled work for one-half the pay.

The ups and downs of mining, even on the Rand, are well illustrated by the history of the past two years of the New Unified mine. Some time back this mine was run at a loss, and the shares stood at 3 to 4s. each. A combination of good management and richer ore has brought the mine up steadily, so that today a profit of £3000 per month is being earned. Dividends are now in sight. The shares have risen with the profits, and in spite of the depression they now stand at 18s. each. The Nigel mine, in the Heidelburg district, has been doing so well lately that people are looking forward to increased activity for the whole district. So far this is the only successful mine in this part of the



Map of the African Goldfields.

country. It appears to be an oasis in an otherwise goldless desert. Much money has been spent in the Nigel district in developing payable mines. Now that the Nigel is doing so well, many feel inclined to try their luck again. For about the first time in the history of the Rand there is an abundance of Kaffir labor. So plentiful is the supply just now that the mines are refusing to take Kaffirs on unless they sign contracts for twelve months. This is a great advantage, for heretofore, when the Kaffir had everything his own way, he would not work longer than six months at a time.

DENVER, COLORADO.

Grazing Regulations. — Clear Creek. — Faker Sentenced. — Cripple Creek. — Conviction for Ore-Stealing.

The grazing regulations made by the Secretary of Agriculture have been upheld by the United States District Court at Denver in several recent decisions. Stock men whose cattle graze on the Government forest reserves must pay fees to the Government. The first decision established the validity of the regulations in the State of Colorado. Similar cases have been tried and won by the Government in Montana, South Dakota, Idaho, California, and Arizona. The stockmen raised the contention that the Government was no more than a private land-owner in the matter of State fence laws. The fence law of Colorado makes it impossible for persons to collect fees or damages from owners whose stock stray upon unfenced land. That the national forest reserves, although unfenced, are not subject to State laws is now well established.

The tunnel propositions in the Clear Creek district are unusually active. The Hall tunnel, which was started several years ago for the purpose of draining the Colorado Central mine at Georgetown, has been taken under bond and lease by local parties. The Burleigh Mining & Leasing Co., of Silver Plume, is constructing an aerial tramway from the Seven-Thirty dump to the Pelican mill, which has been remodeled and has had its capacity increased to 250 tons per 24 hours. The mill is also connected by tramway with the Pelican dump. The Pendleton Gomer M. & M. Co. has been organized by Idaho Springs parties to operate the mines known by the company's name in Russel gulch. At Central City the Jumbo M. & M. Co. has temporarily suspended operations, owing to the excessive quantity of water encountered at this time of the year.

Another faker has been caught and convicted by the postal authorities, namely, J. J. O'Hara, who advertised and sold the stock of the Goldfield Independence Mining Co., in October, 1906, and succeeded in swindling several eastern investors. He has been living in Denver of late, transacting business under the name of the Modern Investment & Securities Co. O'Hara was sentenced to one day's imprisonment, $500 fine, and the costs of the case, which will amount to about $12,000.

The Cripple Creek deep drainage tunnel was advanced 262 ft. during April, which was 40 ft. less than the record for March. The tunnel is in very hard ground, and recently considerable water has been encountered. The intermediate shaft is down 240 ft. It was sunk 99 ft. during April. At the deferred annual meeting of the stockholders of the Dante Gold Mining Co. in Colorado Springs, the former management was re-elected, and the best of feeling prevailed. The president of the El Paso Con. Gold Mining Co. has announced that all El Paso territory will be leased, despite the protest of J. F. Burns. Over 100 applications have been made for the few remaining blocks of ground. W. C. McKelvy has secured a two years' lease on the Black Jack claim on Rosebud hill. Another mining company to operate in Cripple Creek has been formed at Colorado Springs. It is known as the Block Mining & Leasing Co., and is capitalized at $50,000. Charles Anderson, who was the first man convicted under the law making ore-stealing grand larceny, is making determined efforts, through his attorney, to escape the penitentiary. Under the latest ruling he must go to jail while the constitutionality of the law is being determined.

During the month of April Leadville produced 64,000 tons of ore, which was less than the same month of the preceding year, but a slight increase over the month of March. Operations on the Garibaldi have again been resumed. This property was closed down in 1885 and has so remained until the present company took over the mine with a view to developing it through the old adit in California gulch. When formerly worked, the property is reported to have paid handsomely, but owing to failure to obtain right-of-way through certain grounds not owned by the former operators, the enterprise was finally abandoned. The new company will drive the adit to the Sunday vein, which they hope to reach after driving 1000 ft. farther, and will then reach a depth of about 800 ft. It is then proposed to raise to the bottom of the Sunday shaft, which now has a depth of 500 ft. The new organization is called the Ball Mountain Tunnel & Mining Co., and is composed principally of local mining men, among whom are M. A. Nicholson, Percy Hannu, L. A. Reynolds, Geo. E. Keeler, and W. Marrell. After remaining comparatively inactive during the winter, there is now much work in progress on Fryer hill. Among the old properties the Forepaugh, Robert E. Lee, and the Rupp have resumed. Also the Chrysolite mine, controlled by J. S. Shepherd and associates, has resumed and regular shipments are being made. On the Louise property in South Evans gulch, the shaft is being sunk, and at a depth of 400 ft. levels will be driven. The rich ore struck on the Catawba claim, on Canterbury hill, grows wider as the shaft is deepened.

SALT LAKE, UTAH.

Silver King Coalition. — Prince Consolidated, Pioche. — Park City Mines Merger. — Consolidated Mercur. — Bingham Production. — Ohio Copper.

At the annual shareholders' meeting of the Silver King Coalition Mines Co., operating at Park City, the retiring board of directors was elected, which organized with the same officers. The treasury contains about $200,000. Since last autumn production has been upon a reduced scale, but preparations are under way to increase the output. A suit will be filed in the Federal Court in a few days against the Silver King Coalition Mines Co., the Silver King Consolidated Mining Co. being the plaintiff. The defendant will be charged with having trespassed within the domains of the plaintiff, extracting therefrom a large tonnage of ore. Efforts to effect a compromise have so far been without avail.

Ore shipments from Park City last week were 190 tons from the Daly Judge, and 567 tons from the Silver King Coalition mine.

Talk of a merger between the Ontario, Daly, and Daly West, at Ontario, and the Naildriver, at Park City, has been revived, and negotiations are said to be actually pending in New York. This combination was planned about the time of the Ontario drain-adit disaster, about three years ago, which delayed the carrying out of the plans until now.

The annual meeting of the Consolidated Mercur Gold Mines Co., has been called for July 6 at Jersey City, N. J. The management gives out the information that dividends will be resumed before the end of the present year; that physical conditions are better at the mine now than they have been for several years, and that addition to the surplus is being steadily made. A shipment of $64,480 worth of gold bullion was made to the U. S. Mint at Denver last week, representing all but about $2500 of the April production.

Ore shipments from Bingham are heavier now than at any time in the history of that camp. Aside from the big copper producers, several of the smaller mines have resumed operation after several months' shut-down. The Utah Copper Co. is moving 100 carloads per day to its concentrating mills at Garfield and Copperton; the Boston Consolidated, 25 carloads to its concentrator at Garfield and 5 cars to the smelter direct; while the Utah Consolidated continues to keep up the average of 16 cars, or 800 tons, per day. The daily output of the Bingham district is now between 10,000 and 12,000 tons.

Salt Lake mining machinery dealers have been sending much mining equipment to Pioche, Nevada, lately, which camp seems to be prospering. Conditions have materially improved in the camp of Alta lately. The Columbus Consolidated has resumed operation of its mill, and is about to inaugurate regular ore shipments again; the Consolidated Flagstaff property has been taken over by the Flagstaff Copper Co., and development work will be started shortly; the control of the old Emma mine has passed to Jesse Knight of Provo, who will direct its development; and the South Columbus company is still conducting development and will begin ore shipments in the near future.

BUTTE, MONTANA.

May Output. — North Butte Contract. — Summit Mountain. — Trenton Co. — Butte & London. — Corbin Consolidated. — Continental.

The Continental mining district, a few miles east and south of Butte, is again receiving attention, and the belief expressed by Government geologists that the district contains the mother lodes of the big veins of the Butte district will be tested. Michigan and Montana men have organized the Lion Gulch Development Co., which has taken over the property of the Gold Flint Mining Co., situated eight miles southeast of the city of Butte and three miles north of Homestake, on the Northern Pacific railway. The new company will sink a shaft 1500 ft. deep. New machinery will be installed and men are at work building a road to the Northern Pacific track and erecting houses and cabins.

The old Ruby gold mine, 18 miles northeast of Butte, formerly owned by W. A. Clark and others, is again a good producer. Patrick Dowling, a Butte miner, took an option on the mine a year ago for $75,000, and almost immediately he opened up a good body of ore, from which he has paid for the mine, added new machinery, and is now re-building an old mill. He is also erecting an up-to-date cyanide plant with which to treat the tailing. As much as $12,000 has been received by Mr. Dowling from a single carload of the ore. The ore-shoot is about 150 ft. long and from 10 in. to 3 ft. wide. Several thousand tons of low-grade ore on the dump will average $10 to $20 per ton.

In May the mines of the Butte district produced about 27,537,300 lb. of copper from 346,425 tons of ore. The mines have probably now reached their high mark of production. The various companies contributed to the May total as follows:

Companies.	Tons ore.	Pounds copper.
Boston & Montana	105,400	8,432,000
Anaconda	110,050	8,253,750
Butte & Boston	10,850	759,500
Washoe	10,075	705,250
Parrot	10,850	737,800
Trenton	6,200	403,000
North Butte	40,300	4,030,000
Butte Coalition	31,000	2,480,000
Original	15,500	1,240,000
Miscellaneous	6,200	496,000
Total	346,425	27,537,300

The new smelting contract between the Anaconda Copper Mining Co., operating the Washoe smelter, and the North Butte Mining Co., became effective June 1. Under it the North Butte gets a concession of 50c. per ton, an approximate saving of $700 per day. It is understood that the Butte Coalition Co. has a similar contract with the smelter.

The North Butte Co. is cross-cutting to the veins from the 2000 and 2200-ft. levels of the Speculator shaft. The lowest depth at which mining is being done at present is on the 1800-ft. level, where both the Jessie and Edith May veins have been opened. Driving on that level is progressing, and the veins are found to continue extremely rich. The North Butte, like other companies in the Butte district, recovers much silver and gold from the copper ores, enough to pay about half, or more, of the entire cost of labor and supplies. The North Butte, for instance, gets about $60,000 a month in silver and $4500 in gold.

A number of mining men, engineers, and geologists have visited the new copper discoveries in the Summit Mountain district, near Buxton, about 10 miles southwest of Butte. The country has not yet been sufficiently developed to demonstrate any great depth to the orebodies, the deepest workings being only 130 ft. The properties are situated in typical Butte granite country. There is a mineralized zone about half a mile wide through this granite, having one eruptive dike of porphyritic rhyolite or quartz porphyry, which has been explored for a distance of 6000 ft. Three or four veins have been explored.

The Trenton Mining & Development Co., one of the Amalgamated subsidiaries, has made an annual financial statement showing a paid up capital of $1,000,000 and assets amounting to $1,800,000, with an indebtedness of $55,500. The Trenton operates only the Gagnon mine, a low-grade copper property, but having high silver and gold content. The Butte & London Copper Development Co. in its annual statement shows a paid up capital of $5,000,000, and assets, including cash and stock in the treasury, of $5,439,527. The company was recently forced to suspend work for lack of sufficient funds.

The Corbin Consolidated Mining Co. has been organized and incorporated for the purpose of operating in the Corbin district. The new company is capitalized for $500,000, divided into 100,000 shares at $5 par. The directors are J. L. Meixell, S. L. Case, D. M. Armstead, H. K. Welch, and M. B. Jenkins.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Dredging in New Zealand.

The Editor:

Sir—In a late issue of your valuable paper I saw a brief article on gold dredging at Waipori, New Zealand.

The dredge is stated to have cost £3500, or about $17,000, to have handled 212,000 yd. in 45 weeks, at an apparent cost of 6.7c. per yard and with a saving of 11c. per yard. The gravel figures out to have been 4 yards deep. What I would like to find out is what type and make of dredge this was.

The costs are sufficiently low for a larger boat, the depth of gravel very small, and the stated dividends on the total operation in all about $50,000 above the costs of the boat, etc. There are many localities where such a small installation would pay very well, but I do not know of any company building such an effective machine, therefore the details would be interesting.

JAS. W. NEILL.

Pasadena, April 29.

[We hope one of our readers in New Zealand will send us information on this subject, and particularly as to the character of the gravel dredged. Such light construction as the low price would indicate suggests that the conditions were not severe, and that the gravel was probably quite loose and free from boulders of the size commonly encountered in ordinary dredging operations.—EDITOR.]

The Whiskey-Water Barrel.

The Editor:

Sir—Having just returned from a professional visit to one of Nevada's new mining camps, where water is hauled 12 miles from the railroad station in whiskey barrels, I write to ask, in the interest of prospectors generally, and of occasional visitors to such camps, if among your friends there is anyone who has enough knowledge of the chemical reactions that take place in a whiskey barrel to suggest a remedy for the awful taste that such barrels give to the water. While this taste is as lacking in substance as things in "The dream that I dreamed I was dreaming," yet it is as persistent and searching as the alkali dust on White Plains in summer.

On this trip I found a prospector who claimed to be Mr. Harriman's partner. On being asked for an explanation, he said that on one of his trips he found a mine and shortly afterward learned that it was on railroad land. The old prospector seemed to feel that he would not receive from his partner, Mr. Harriman, the consideration that he would be sure of from a partner whom he could reach and shake hands with. Up to this time, Nevada's prospectors have as a rule selected a line 20 miles on either side of the railroad for their prospecting, as they have had no means of knowing which were the odd and even sections, and they, as a class, were not given to taking chances with partners the color of whose eyes they did not know.

Next to the whiskey barrel question, I think your desert friends would be glad to have you throw light on the attitude of the railroad companies toward prospectors who discover mineral of value on railroad lands.

Stockton, Cal., April 27.

Mining Education.

The Editor:

Sir—The letter by Mr. John A. Reid in your issue of January 18 has brought beyond the saturation point my interest in your original (in two senses) suggestion at the dedication of the new mining building at the University of California; and some of it has crystallized out. Allow me also heartily to second your suggestion. The need of some such arrangements is so obvious that it is not worth while to say more; the details of a plan to put it into effect are not properly our concern. So let me comment on some aspects of the proposed arrangements from the professor's standpoint.

In choosing a college professor it may be accepted that in the first place he should be a man of high standing in the theory and practice of his profession. In addition, he must be an educator, that is, one skilled in the art of imparting knowledge to others. A further quality desired by all institutions, and demanded by the larger ones, is the ability to perform and direct research work. A triple benefit is derived by the school from this: the published researches of its faculty draw attention to it and give it standing; the intrinsic worth of the man is increased by his original work; and it is not illogical to assume that a man who can do original work in science can develop his department along original lines. There is, at times, a tendency for schools to get top-heavy in the matter of research, just as students often spend more time on athletics than is required to keep them in the best physical condition, but in neither case is it practicable or wise to cut down the amount too much. The professor must be executive enough to administer the funds of his department to the best advantage, and diplomat enough to secure advantages for it without antagonizing trustees, faculty, or students. A most important final quality is the possession of personal traits such as will make him agreeable to his associates—best summed up by saying that he must be a gentleman.

Supposing that we have caught a perfect specimen of this kind, let us follow his life through a few years in order to observe the forces acting on him and their effects. With the advent of autumn we find him lecturing to classes, overseeing laboratory work, directing the research work of his graduate students (which usually means doing the larger part of it himself, except the manual labor), and whipping into line that never-failing portion of the class that fails to see why they should not be allowed to skip the work of the first two years, begin with the advanced lectures in mining and metallurgy and so,

like Jonah's gourd, blossom forth in a night. Besides this, there are the special arrangements to make for men coming from other schools (no small matter in a large school), the committees in endless variety, each of which demands both time and mental effort. Then there is the preparation of papers and lectures for learned societies, the carrying on of some favorite research, the thousand and one small social duties that the 'practical' fellow managing his mine halfway up Lone mountain is blissfully unconscious of; and if our professor can squeeze in a few games of tennis, and a night or two at the theatre to keep his system and intellect normal he is to be congratulated. If he is conscientious about keeping up with the periodical literature of his profession, perhaps he will be able to manage it while waiting for his breakfast or going to his work in the street-car or train.

With the summer months there comes a summer school. The arrangements for this have been crowded into the winter's work, and the work of it uses up the larger part of the summer. What little is left will be devoted to a bit of professional work, to bridge the gap between the small salary and the large interests of the man. Year after year passes thus, each adding to the entangling mesh of small duties, which, unless carefully restricted, will soon hamper his larger work. Last year's lecture notes will have to do for this year, because there is no time to revise them; until they get to be the notes of ten years ago. He views with dismay the pile of unopened periodicals on his study table, and bribes his small son to open and pile them up. He wonders will he ever get the time to see that new process in operation, away off in the back corner of Mexico, while South Africa and Australia are as far away as the New Jerusalem.

Eventually he gets a sabbatical year, if he is fortunate enough to be at one of the few institutions where it is actually given. But his good fortune will probably not extend so far that there will not some special duty arise to demand his time, or perhaps something goes wrong in his department, so that he cannot leave that year. Pretty soon his joints get stiff, and climbing mine-ladders is no longer as easy as it once was. By this time his kind friends will have begun to dissect him with caustic criticism because he is "too theoretical."

The proposed arrangement would remove all this at one fell swoop. The absence from the school would prevent the hampering by petty duties. The conduct of the work by another man during his absence would prevent the persistence of any features in the work of the department that are not justified by general experience. Above all, the time devoted to travel will enable him to gain a first-hand knowledge of the operation in every phase of his profession to a degree that is now impossible to even the most widely traveled consulting engineer. The desirability of this is so obvious as to need no comment.

A word more as to the entire justice of the criticisms so frequently heard of the college professor and what he accomplishes. In the first place, it is amusing to note that there seems to be a more or less general belief that the college professor somehow is not just the comomn variety of man, but a sort of *lusus naturae*, that has sprung into being in some unknown and adventitious way. There is a typical sort, well known in comic journals and to the 'practical' man, although in an academic experience from Manhattan to Cathay I have never encountered one. Mr. Reid's description is strikingly graphic. I can see this professor as he sits immersed in books, his pallid brow lit by the flickering study-lamp, while outside pulses the "deep throbbing life beyond college gates" of which he "never comprehends actual living conditions in the larger world of labor!" I can also see the expansive smile on the faces of such men as J. F. Kemp, E. D. Peters, and others, as they read it. I wonder why people believe in sea-serpents, typical college professors, and other freaks? Did anyone ever really see one?

The real facts of the case appear to be that the typical college professor is an ordinary sort of man, peculiar only in that he believes it better to be useful than to be rich. He has generally had a wide experience in practice before devoting himself to teaching, and would always devote some of his time to practice, if that were practicable. The criticism that his teaching usually is not sufficiently close to present-day practice is just, though frequently exaggerated. It is an inevitable result of the present state of affairs. A man perfectly equipped for teaching if he devoted himself wholly to teaching would in five years be just five years behind present practice. Something can be done to prevent this by keeping closely in touch with the periodical literature of his profession, but for purposes of instruction this is quite inadequate unless supplemented by frequent visits to the scene of operations. The head of a department usually has but little time for the former, and none for the latter. Mr. Rickard's suggestion covers the case amply.

While Mr. Rickard is bearing the aegis for the head professor, let me say something regarding the younger men in the department, who presently become head professors, in the same or another school. Several of our technical schools have the vicious habit of appointing members of the senior class as laboratory-assistants, and promoting them slowly with small increases of salary, in a semi-military fashion, until in their old age they attain the headship of a department. This is a two-fold mistake; the slow promotion causes the ambitious men to try their fortunes elsewhere, and the inbreeding that results from putting men in charge of a department that have themselves been trained in it, is absolutely certain to develop a case of intellectual cretinism. Nothing could be better devised to prevent the free growth of the school. As far as is practicable the placing of recent graduates of a school on its own teaching staff should be avoided. Another thing needed in most schools is a larger salary for the younger men, large enough so that the present persistent temptation to leave teaching for more lucrative work shall not be so powerful. A young man of means without responsibilities can afford to ignore this, but the best men are frequently

without means and with responsibilities. A great deal has been said about the small salaries of college professors, but after all this is not so remarkable a matter as might appear. When men work for the love of their work and not for the money there is in it, it is to be expected that their salary will be largely paid in the commodity they most desire.

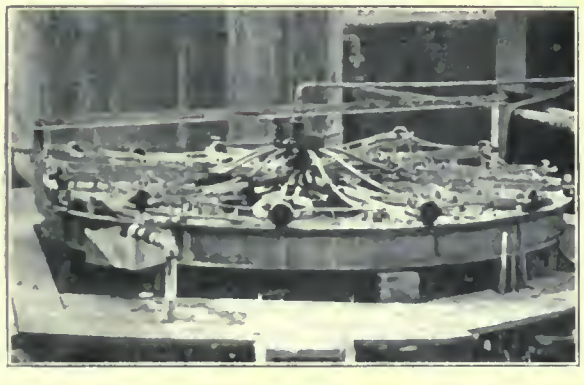
The Ridgway Filter.

The Editor:

Sir—I am enclosing photographs of the Ridgway filter, hoping that they will be as interesting and instructive to your readers as the machine itself was to me. This particular machine is placed in the Pastita cyanide plant of the Guanajuato Development Co. as an initial unit, to be supplemented by others after this one has demonstrated its ability to treat the slime. These filters are all set up in the factory in England before shipment to customers, and the mechanical operation of the filter (*not* filtering slime) is perfected. The machine is beautifully made. I



The Ridgway Filter in Elevation.

am not violating confidence in quoting Mr. Joseph MacDonald as saying that it is an almost perfect machine from a mechanical point of view. The filter leaf is a flat iron plate cast with corrugations on its under surface. This under surface has an area of over three square feet and is covered with canvas, which serves as the actual filtering surface. These leaves, 14 in number, are arranged to be lowered into pulp during part of their revolution, raised over a partition, and lowered again into a second trough. This second contains water (or solution) for displacing the retained metal-bearing moisture in the slime. The raising and lowering is effected ingeniously by the irregular arrangement of the outer track upon which the leaves are supported. At the moment that the leaf is lowered into the pulp after passing the discharge-hopper the vacuum-valves open automatically. The air-pressure valves are to be opened by a roller-cam when the loaded leaf reaches the discharge-hopper and these valves are timed to the fraction of a second, as are the vacuum-valves. Three of these leaves are continuously immersed in pulp. The compressor that provides the compressed air for discharging the slime is of English manufacture and is well made and efficient. The vacuum-pump is a double vertical supplied by the Cyanide Supply Co., of England, and is the proverbially well made, neatly finished, and efficient machine from English shops. I omitted to mention that the slime and wash-solution compartments are provided with 10 slow-moving agitators driven through stuffing-boxes from below by a series of cut gears of excellent workmanship with probably very slight friction and wear. The machine has been erected and ready to run for several months, and I cannot emphasize too strongly the excellent workmanship, construction, and materials used.

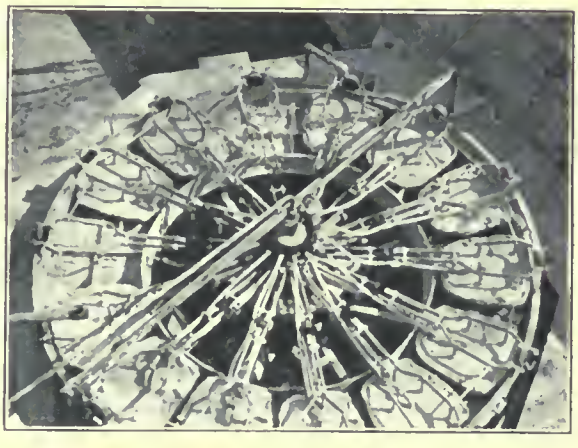
Submerged Facts and Filters.

The Editor:

Sir—The fact that mining and metallurgical publications have, during the past few months, contained several articles and advertisements relative to the exclusive ownership of submerged filters and the details of their construction and operation, suggests



The Ridgway Filter in Plan.

that something may yet be said, without impropriety, by those on the outside.

There is no general opposition to the proposition that the man who shows to his fellow-workers a better method or mechanism should receive compensation through the patent laws for the novelty involved in that service, but the public justly resents the patenting of ancient and generally used methods.

Submerged filters long since outgrew protection under patent laws. I made my first acquaintance with them in the year 1865, when the knapsacks of soldiers returning from the civil war were opened for the inspection of the boys at home. A porous clay block, connected with a mouthpiece by a rubber tube, enabled the soldier to lie down by any muddy pool and get a drink of clear water. It may not be unreasonable to assume that no filtering has ever been done without submerging the filter, as the outer and inclosing wall of liquor, however thin, is always present during filtration.

About thirteen years ago millmen were working upon the problem of the separation of slime from liquor in cyanide practice. My own efforts in that direction date from that time, and I remember with

more amusement than pride the variety and extent of the scrap-piles that mark that particular pathway. After going to the limit in centrifugal separation, I turned to suction, and drew the liquor through all kinds of filters into cylinders, cones, and boxes, removing the adhering slime-tailing by various devices. Perhaps others approached more closely to the achievement of a sensible working plan and mechanism than I did, but my own methods and appliances were, in the light of the present, crude and not feasible.

In my opinion, George Moore's great service to the cyanide milling industry consists in his truly valuable conception as to the size and shape of filter-cells, making possible the assembling of large filter-area to be handled as a unit. Slime treatment in American metallurgy was not successful until Mr. Moore gave us his shape of cell, and that form of filter-cell remains a basic principle in the present perfected vacuum-filtration. The many mechanical imperfections in the early construction defeated his purposes and, in his first important test, at Mercur, Utah, condemned his process.

The writer, believing that Mr. Moore had outlined the best system for slime-filtration so far discovered, and that the bad mechanical features could be corrected, advised J. V. N. Dorr to investigate the process and to install it in the Lundberg, Dorr & Wilson mill, then being built near Lead, South Dakota. After study of the Moore slime method, it was adopted by Mr. Dorr, and at his mill the first success was made with the system. Mr. Dorr eliminated much of the original crudeness of the Moore plant, but even after his improvements were introduced there was trouble at various points, and the filter-cells remained so unsatisfactory as to threaten the final condemnation of the Moore slime process.

After study of the process as operated by Mr. Dorr, I was convinced that Mr. Moore's inspiration as to the external shape of filter-area made success possible for vacuum-filtration in cyanide practice, and that his cell construction must be radically changed, and his plant for freeing the filters from the adhering slime-tailing greatly improved, before his system could become useful. Immediately after my observation of the work at Mr. Dorr's mill, I made and used the first perforated iron-pipe framed filter-cell that was ever designed or put into service, and for the internal air-pressure adopted by Mr. Moore for discharging the tailing, I substituted internal liquor-pressure under low head.

The fact that the iron-pipe cell-frame and the internal liquor-pressure are vital to the success of the system in question; and that those new features retrieved from failure vacuum-filtration as applied to cyanide mill-work, have been proved by the failure and abandonment of Mr. Moore's cell-frame and internal air-pressure, and the adoption and present general use of my perforated iron-pipe cell-frame and internal liquor-pressure.

Since satisfactory results in operating filter-cells are dependent upon the incorporation of these latter features, the two leading vendors of slime-filter plants and mill-rights are using them, although both of these companies know that the points are covered by my patents.

The foregoing may have been, hitherto, a submerged fact to many users of my iron-pipe cell-frame and internal water-pressure, but as that fact is soon to become a subject of agitation, and as the matter is of considerable importance to mill-managers who are employing the filters in question, it seems proper at this time to make the above statement.

G. A. Duncan.

Nelson, Nevada, April 22.

Life-Saving Apparatus.

The Editor:

Sir—In your issue of April 4, under the heading 'Concentrates,' you say "Helmets such as are made for rescue service in mine-fires are not trustworthy and are good only for short periods of time. As built they are too cumbersome and hinder the vision of the wearer." It is admitted that many of the types of helmets now used are open to adverse criticism because of the faults mentioned, but it is hardly fair to class all types together and to condemn them as a whole. The following description is an account of efficient work performed in a fire in the Schoenberger mine of the Pittsburg & Westmoreland Coal Co., near Pittsburg, by the Draeger life-saving apparatus.

The fire started on December 23, 1907, and had the Draeger helmet been brought at once into use it would, in the opinion of many of the coal company's foremen, have been possible to stop the conflagration in a short time, with a consequent saving of much money. The situation underground, when the stoppings had to be put up, can be best comprehended from the enclosed illustration. The first opening of the second wooden door (in order to approach the place where the intended stopping or bulwark had to be put up) was made on Tuesday, April 7. An enormous amount of dense black smoke and a very great heat was found inside; at the same time the place was so muddy that the men wearing the apparatus sank nearly up to their hips. The first intention was to put up a stopping made out of mud and cement, which was supposed to get dry in a short time on account of the enormous heat. After some exploration work, which showed the fire burning at a distance of about 20 ft. from the intended stopping, and after working on this stopping for a while, the supply of oxygen ran out and the work had to be abandoned.

On the morning of the 10th at 1 o'clock a sufficient new supply of both oxygen and cartridges had arrived from New York, and work was resumed at once. On re-opening the second safety-door it was found that the fire had made headway to within 8 ft. of the place where the stopping was to be erected. The dense black smoke had disappeared and the fire gave good strong light, so that the men could see very well, especially as the electric safety flash-lights and hand-lamps were aiding them. This was a great advantage, because at the first trial on Tuesday only the Draeger safety-lamp gave a sufficiently strong light to penetrate the dense smoke. A further ad-

vantage was the fact that on account of the enormous heat the mud had dried, and therefore the men were able to move around more easily.

Conditions being more favorable, it was decided to erect a wooden stopping; this was done after about an hour's work, and it proved so air-tight that the solid brick stopping, which was then put up, could be worked upon without wearing apparatus. The whole work was done by men who had not even seen the Draeger apparatus before putting it on, and none of the men, notwithstanding the fact that they had to work in a heat of 130 to 150° for a considerable time, felt any the worse for having worked with the apparatus when putting up the wooden stopping, and they were afterward able to put up the brick wall. By administering pure oxygen to the men from time to time, when the enormous heat had weakened them, a great relief was felt, and not enough importance can be given to the fact that all coal mines should keep a small supply of compressed oxygen always ready for use on such occasions.

W. E. Wingramm.

New York, April 15.

Valuation of Mining Shares.

The Editor:

Sir—The communication of Mr. Newton B. Knox on valuing mining shares deals with the subject which is most vital to the existence of gold mining as a permanent and profitable business.

With the exception of a few restricted areas where certain persons still attract the unwary by a sort of mining slap-stick performance, goldfields are now generally exempt from mere wild-cat speculation. Certainly the great mining fields of the Witwatersrand is the last against which the charge of wild-catting can be brought. There technical advice has been the soundest, and mining methods have ever been the most elaborate, expensive, and modern. Volumes have been written concerning ore-reserves, and columns of figures relating to Rand mining costs have for the past fifteen years adorned the pages of technical and financial journals. Therefore the data recently published by G. A. Denny, and by the General Committee of the Transvaal Chamber of Mines, generally unfavorable to the future of the Rand mines as a field for investment, are unwelcome to the persons most directly concerned, and a surprise to the public as a whole.

Mr. Knox notes the failure, on the part of many investors, to appreciate that in gold mining ventures, the payments annually retired to sinking fund cannot be assumed to draw large interest. It is generally and justly considered that a gold mine must pay from 10 to 20% per annum on the investment besides redeeming the whole capital required, the difference in the amount of interest required depending on the situation and life of the mine considered. But to assume that anything above ordinary bank interest can be obtained on that proportion of the annual returns which is set aside to redeem capital is undoubtedly wrong.

Estimates of the gold production of the Rand have been made by several different authorities since 1893. In that year Mr. Hamilton Smith estimated the future production at £325,000,000, basing his figure on the probabilities indicated by the development at that time. Messrs. Hatch and Chalmers estimated a future product in 1895, of £700,000,000 to a depth of 3500 ft., taking a considerably higher recoverable value per ton than is now conceded. The estimate made in most detail was that of Messrs. Leggett and Hatch in 1904. Assuming that the annual product would be £30.000,000, that the main reef would be worked to 6000 ft. vertically for a length of 46 miles, the life of the field would be 42½ years, and the product subsequently to 1902, £1,233,560,709.

Considering the Rand as a whole, with 66 companies producing gold, the product up to the end of February of the present year had been slightly over £200,000,000. Although gold has been produced since 1884, no operations of great magnitude were begun until 1893. Allowing for the interruption of the war, the Rand has had a practical producing life of 13 years. Using as a basis of computation the Report of the Mining Industry Commission and the figures quoted therein from the Report of the General Committee of the Transvaal Chamber of Mines, it appears that the average future life of the 64 producing mines operating at the end of 1906 was 12.66 years. For the establishment of these mines £29,234,836 had actually been subscribed, not allowing for the excess capitalization caused by the rise in the price of shares subsequently to the formation of the companies.

Up to the close of the financial year of 1906, 39 of these companies had paid £38,132,657 in dividends, 25 not having reached the dividend-paying stage. Against the dividends paid must first be charged the payments to sinking fund before interest can be allowed.

As the above figures represent what the Rand mines have actually accomplished, according to the latest authentic data, what is the outlook? Taking into consideration the unfavorable labor factor, which unfortunately is largely beyond the control of the technical advisors, it is not likely that a capitalistic regeneration of the Rand, necessary to the opening of new mines, excessively deep levels, etc., will be forthcoming. Consequently it is fair to consider the life of that territory on the basis only of those mines already opened, equipped, and producing. It is reasonable to allow a life for these of 12 years longer.

Assuming a total life of 25 years for the producing mines, and the total necessary working capital at £30,000.000, a very moderate estimate in view of past expenditure, it appears to me that a justifiable approximation to the actual conditions in this goldfield is given. In order to return 10% on a 25-year investment of £30.000.000, plus the amount necessary for amortization at 3%, the sum of £3,822,000 must be annually paid as dividend. The total in 25 years is £95,550,000. In the past 13 years the dividends should have aggregated £49,686.000. The actual dividends to the present are approximately £43,000,000. Thus in the next 12 years the sum of £52,550,000 must further be paid out in dividends in order to

make up the required total. Taking the total gross output to the present as £200,000,000, and for the future reekoning an annual tonnage of 18,000,000 tons at 30s. per ton gross reeoverable value, we should expeet as the gross recoverable amount in 12 years to eome £324,000,000, or as the total for the assumed 25 years, £524,000,000.

In other words, the annual dividend requirement would on this basis amount to 18.4% of the amount produced, figured on the whole life of the field, the other 81.6% being the amount allowable for expenditure as working cost. How does this requirement eompare with the results? Up to the present the working cost and disbursements other than those allotted as dividends have consumed only 78.5% of the gross. This figure is a less amount than is allowable for the eurrent expenditures of production; in fact, for the future, owing to the enormous tonnage handled, an allowance of 83.8% ean be made as the proportion of the whole, applicable other than as dividends. This is of course providing that the total future produetion comes up to the figure above given. Only 38% of this product has so far been fortheoming, although 52% of the time has elapsed. Granting, however, that the future produet continues at the present rate of £27,000,000 annually, and is maintained for 12 years, the Rand would appear, on the £30,000,000 eapitalization basis, to fulfill the proper eonditions for a 10% long-life investment.

It will be granted that the conditions assumed for future tonnage and yield of the ore are as liberal as one is justified in allowing. But apart from these considerations, how many other faetors must the average Rand investor look to. In 1906, according to the authorities above referred to, the total eapital invested in the shares of the 64 mines was £70,496,-408, or more than double the amount of money represented by the par value of the shares. Aecording to the list of eompanies given in the 'Mining Year Book,' the highest value of the issued shares in 1901, of the 61 eompanies most nearly representing those now produeing, was a total of very close to £100,000,-000. This is praetieally the highest valuation attained at any time in the past.

How serious a matter, from the standpoint of the investing publie, the inflation of the shares of these eolossal enterprises is may be easily eomputed, taking the period from the close of 1901 to the elose of 1919, say 18 years, as a life, and £100,000,000 as the capital on which 10% interest plus 3% amortization must be paid annually.

Today, the total capitalization represented by the current price of shares of 63 produeing mines is £63,600,000. In order to amortize this capital at bank rate and pay annual interest of 10%, annual dividend of £10,843,800 would be required from now on, implying a total gross production, allowing eurrent expenditures to use up only 78.5% of the whole, of £605,235,350, or in other words a greater total production in the next 12 years than the total possible produetion in 25 years.

Aside from the intrinsic possibilities of the Rand, it is also a matter for concern that at the very time when strenuous efforts are being made to reduce working costs below 20s. per ton, the Mining Industry Commission introduces a discussion of the labor problem, accompanied by no satisfaetory reeommendations as to its solution. For all the voluminous exhibits of the commission in favor of supplanting the black by white labor, no very eonvineing arguments as to the ineffieiency of black labor are advaneed. Referring to one of the reeommendations, it is pretty safe to say that the time when the black miners of the Rand are replaced by one-quarter the number of happy Californians is a long way in the future. The deerease in value of the ore as depth is gained is a factor of ever increasing seriousness. Gold mining fields afford few precedents to indicate that the value of ore remains eonstant with depth. Those deep-level mines of the Rand whieh ean maintain an average reeovery of 30s. per ton until their ground is exhausted will probably represent the exception rather than the rule. And it does not seem likely that over the whole field we may look forward to the time when ore eontaining under 25s. per ton reeoverable value will be regarded as payable.

In individual instances there are undoubtedly still to be had sound investments among the Rand companies. Especially is this so in the case of eompanies holding large rather than small numbers of elaims. In the case of large acreage holdings, the danger of oeeurrence of large and irregularly dispersed areas in the reef, 'patches' as they have been called, of ore below the pay-limit, is minimized. And it is undoubtedly true that some properties are mueh better managed than others, and consequently working eosts are lower. But the investing public whieh reads Kaffir shares at par as paying a fair but not an extraordinary interest, is not going to buy these shares at from one and a half to three times par value, with the knowledge that the life of the investment is not long enough to return the requisite amount in dividends.

One factor tending to the increase of eost of produetion on the Rand may be suggested. The vast industry which has been built up in that field has sueceeded in adding to the world's supply of gold over £200,000,000. A marked inerease in the amount of gold means a world-rise in prices of commodities. The Transvaal, a region isolated from eentres of manufacture, and only partially enriched by those natural resources neeessary to the mining industry, is among the first to suffer from each new rise in the price of supplies whieh it must eonstantly obtain from the great markets of the northern hemisphere.

C. W. Purington.

London, May 2.

Acetylene lamps have many advantages for use in mine surveying. They are free from the grease so troublesome in soiling note books, and the small bright flame is a better 'sight' than the ordinary lamp.

Sulphur constitutes 0.04% of the outer 10 miles of the earth, including in these 10 miles the original roeks, the waters, and the atmosphere. The waters of the oeean eontain 0.09% of sulphur, and the original roeks average 0.03 per eent.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

The word 'fault' is loosely used to indicate not only the fact of dislocation of rocks, but the surface or zone involved in the dislocating movement. There is, however, no warrant to be found in the dictionaries, nor among the best writers, for applying the word to anything more than the dislocation or interruption of continuity of the rocks affected by a disrupting movement.

Finished iron or steel may be softened, without damaging the finish, by the following method: Prepare an iron box lined with fire-clay. In it place the work, completely surrounded and covered by shavings of the same metal as itself. Seal the box tightly with fire-clay luting, heat it gradually to a red heat in a closed furnace and allow it to cool before removing from the furnace.

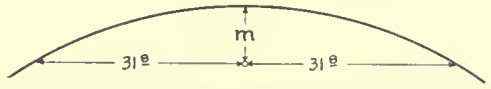
Extra-lateral Right.—The owner of a properly located lode mining claim may follow his vein on the downward course into and underneath the surface of an adjoining mining claim. In doing so, however, he must keep within the plane of the vein, or at least follow it. He cannot leave it and cross-cut into his neighbor's ground, nor run cross-cut tunnels in the property of others simply because this method is the most convenient one for working the claim.

Plasticity in clay is due to the development of a colloidal substance of a gelatinous character which forms from the hydration of aluminum silicate. The particles of this 'colloidal clay,' as it is called, are stated by recent investigators to possess a diameter of approximately one-thousandth of a millimetre, and to have the form of scales, on account of which they acquire a peculiar motion, known as the 'Brownian' motion, in water, which greatly retards the settlement of slime in which this colloidal substance is abundant.

Manganese, as oxide or hydroxide, exists in all deep-sea deposits, sometimes as grains in the ooze, sometimes as a coating upon pumice, coral, shells, and often in the form of nodular concretions around a nucleus. The origin of these nodules is doubtful. Their derivation from the subaqueous decomposition of volcanic debris is the more generally accepted theory. The nodules occur in close association with altered volcanic materials, and most abundantly in connection with red clay of similar origin. In composition they range from 4 to 63% manganese oxide.

Bacterial influences may be present in the upper parts of some veins, but we are not aware of any investigations upon this point. The bacterial fermentation of organic matter present in the vein would have the effect of reducing ferric to ferrous hydrate, and this to a greater or less extent would be dissolved by waters carrying CO_2. The iron dissolved as ferrous carbonate would be re-oxidized to ferrous hydrate in the presence of oxygen absorbed in the solution. It would then be precipitated and would readily form nodules, concretionary masses, or incrustations around open spaces in the lode-matter.

The degree of curvature of an existing track is often desired when no surveyor's transit is available, or without using the laborious process of chords and



deflection angles. By the following method, requiring only a tapeline and a two-foot rule, this may be ascertained with an accuracy dependent only upon the care used. Measure the mid-ordinate, m, (see figure) of a chord 61.80 ft. long. The length, in inches, will be the degree of curve.

Concentration by flotation in the oil-vacuum or Elmore process, depends, first, on the attraction between metallic sulphides and crude petroleum, and second, on the attraction of air or gas for the oil, whereby any gas present will attach itself to the oil-covered particle of pyrite and lift it by 'ballooning.' In practice, water is decomposed electrically in the presence of the oiled sands in a vacuum-chamber, after which treatment a vacuum is produced above the pulp, thus greatly augmenting the lifting power of the bubbles of oxygen and hydrogen produced. Also sulphuric acid may be employed to disengage CO_2 or H_2S when carbonates or decomposed sulphides are present in the ore. Usually 20 lb. of H_2SO_4 per ton of dry sand is sufficient. The acid also cleanses the pyrite, causing the oil to coat it more readily. The scum of sulphides floating on the surface is drawn off by suitable mechanical means.

Mineral wool is the product obtained by forcing a jet of steam or air against a stream of molten slag or molten rock. The molten material is blown out in the form of small spherules from the main stream, each one, comet-like, carrying behind it a thread of the material. Under proper control of the jet of air or steam, it is possible to produce a product having a large proportion of the threads or fibres and only a few spherules. The resulting product is a non-conductor of heat and sound, and is therefore largely used for covering steam and water-pipes, for lining safes, cold-storage plants, partitions, and the like. Mineral wool is most commonly made from slag. The earlier product was objectionable because of the sulphur it contained. When used in damp places the moisture acted on the unstable calcium sulphide in the slag-wool, forming sulphuric acid, which attacked the metals in contact with it. This difficulty has been overcome by re-melting the slag in a cupola furnace, reducing the sulphur to about 1%. Ordinary mineral wool weighs about 12 lb. per cubic foot, and contains 92% voids. It costs in New York about 1¼c. per lb. So-called 'extra' mineral wool weighs about 9 lb. per cu. ft., contains as high as 96% voids, and costs 4½c. per lb. at New York. In estimating the quantity of wool required for filling, allow 1 lb. per square foot for each inch in thickness for ordinary wool, and ¾ lb. for extra wool.

GOLDFIELD, NEVADA.—IV.

Rich Ore and Its Moral Effects.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

Rich ore invites theft. Wherever men find minerals so valuable that a small weight of it represents money, there the temptation to steal is inevitable, the weak guard of conventional morality is broken, and the conscience of the miner is debauched. It does not matter whether it be an old mining community like Bendigo, with its art gallery and botanic gardens, or a younger and richer district, like Kalgoorlie, or an even more recent and more extravagant camp, like Goldfield; in every case the sight of gold, or of the minerals that are known to enclose it, provokes industrial kleptomania. In Colorado and Nevada they call it 'high-grading,' that is, the removal of high-grade ore from the possession of the mine-owner to that of the mine-worker. The man that is guilty is called the 'high-grader' and the purchaser of the stolen goods is called a 'fence,' the word meaning originally a place of defence against the officers of the law. 'High-grading' is larceny.

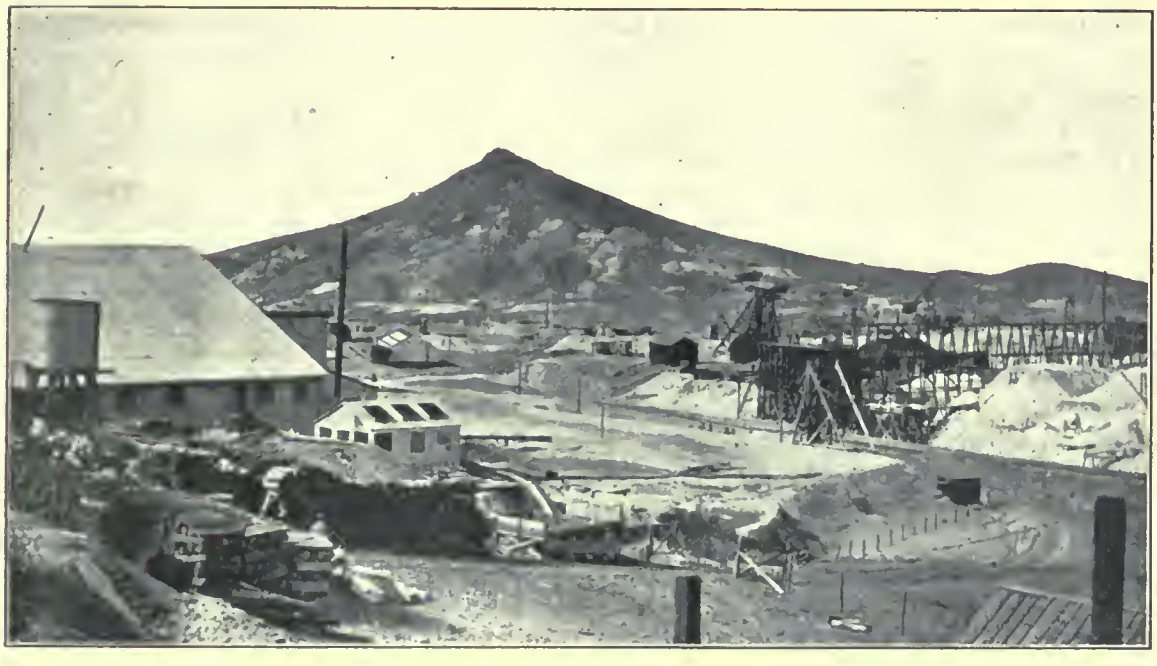
To understand the extraordinary freedom with which rich ore was stolen at Goldfield, it is necessary to appreciate the peculiar labor conditions prevailing in this part of Nevada during the time when the bonanzas in the Mohawk, Red Top, Combination, and Florence mines were being exploited. Mining operations were conducted under leasehold; the owners of the mines were, for the most part, without experience of mining, they had no capital, and they did not know where to look for ore; so they granted leases to parties of working miners willing to work, and to adventurous operators willing to furnish the money for exploration. The areas controlled by different companies or ownerships were sub-divided into blocks, usually 300 ft. long and the width of a claim (600 ft.), and in order to stimulate speculation the lessees organized stock companies, placing the shares on the exchanges of San Francisco, Los Angeles, Salt Lake, and Goldfield. As evidence of the enterprise of some of the men that are mining at Goldfield, I may mention the lease taken by John Donnellan & Co. on the north end of the Red Top. The ground leased is on the south slope of Columbia Mtn. and near the foot of it; the area is 600 ft. square; the term of the lease is 18 months. The lessees agree to sink a two-compartment shaft to 500 ft. They expect to sink at the rate of 150 ft. per month and to complete the shaft within four months. All the money required for this work was obtained in three days by sale of stock. No better proof could be given of the venturesome spirit of the community. Of 100 leasing companies organized in 1906 and 1907, fully 20 struck rich ore and made big profits for a time. Most of them started with just enough money to pay the costs of incorporation and got the capital for their preliminary development by selling shares. Only one of the leasing companies was a close corporation. Even half a lease was incorporated. This happened to the Lewis Rogers lease, one-half interest in which was incorporated as a company of 1,000,000 shares. It only remains for the individual shareholder to incorporate himself. As soon as the incorporators had organized they went to the local or State banks and borrowed money on their stock, the bank in its turn endorsing the company as a legitimate mining scheme. The wonderful ore discovered in the Frances Mohawk, Hayes & Monette, Rogers, Little Florence, Red Top, and other leases sustained the whole fabric of fictitious finance until the day of accounting came last October, during the panic that involved the whole industrial structure of America. Then the local banks (all save one) shut their doors and the local brokers pulled down their stockboards. The total loss among three banks was fully $1,000,000, while the surviving bank (John S. Cook) had $6,000,000 available. The rate of interest paid by the leasing companies was 1 to 2% per month; the bank officials were interested in the leases and in the stock deals that resulted. The one essential factor missing was uninterrupted prosperity and inexhaustible reserves of rich ore.

The ore was rich indeed. In the Frances Mohawk lease at a depth of 200 ft. there was 8 inches of stuff that assayed $250,000 per ton; it was free gold and calaverite or telluride of gold. The various leases on the Mohawk mine yielded a total of $50,000 per day for 106 consecutive days. One carload shipped to the Selby smelter weighed 47 tons and assayed 609 oz. of gold per ton, so that the shipment was worth $591,637, that is, more than $6 per pound. There were many places in the mines where men knew they were breaking ore worth 10 to 15 dollars per pound. It was easy to steal several pounds of ore. And they did.

At the time of my visit there was not much stealing going on—so I was told—except in the Rogers and Little Florence leases, but these happened to be the only ones in bonanza just then! It is estimated that last summer over $1,000,000 worth of ore of which no proper account was made went out from the Mohawk and Combination mines, and $500,000 to $750,000 from the Florence. Not less than $1000 per day of illicit bullion passed through the United States mint at Carson, even after the Goldfield Consolidated mines were closed down, so that most of it must have come from the two Florence leases (the Rogers and the Little Florence). Only $300,000 was recovered last year for the whole camp, despite every effort to find the stolen ore. It is most difficult to trace the 'high-grade,' for the thieves crush it at once and so destroy the chance to identify the product from any particular mine. Unless identified positively, the legal evidence is incomplete. The stolen ore is usually taken to a bogus assay-office, the proprietor of which pays about 50% of its real worth. The ore is then treated by chlorination; first it is roasted in a muffle and then leached in a barrel with a stirrer. In one case a plant was raided while in operation. The heading assayed 260 oz. gold per ton; the tailing assayed 15 oz. Larceny does not wait on accurate metallurgical method. When the owner of this particular establishment was asked what he intended to do with the tailing, he said that this residue would be sold to a man who intended to salt the oxidized

ore on a neighboring claim. Even when the circumstantial evidence seems convincing, the local justices are afraid to convict; public opinion regards 'high-grading' as rather humorous, the labor unions preach a doctrine by virtue of which a little rich ore is the miner's perquisite,* the rush to become wealthy possesses everyone, and in the excitement the moral law is left high and dry.

It was an orgie of stealing. Regular harnesses were invented for carrying ore under the working-clothes of the miners. They would step from the cage or bucket and stumble heavily laden on their way homeward without being arrested, although the officials knew why they walked so clumsily. One day, for instance, when the men were being hoisted to the surface at the Mohawk shaft, a man came up so loaded with concealed ore that on stepping out of the bucket he fell. The superintendent saw it and to strike the pail of one of his own shift-bosses with his candle-stick and detected a solid sound; he asked the man to go to the second level and perform an errand; then he opened the dinner-bucket and found it full of rich ore. Frequently the sacks that hold the wedges used by timbermen were employed as receptacles for stolen ore. The 'muckers' or shovelers would handle their shovel so as to leave the heavy fine ore on the bottom of the level and as soon as the men in the stopes shouted "fire," which they would do 10 minutes beforehand, the shovelers would have a chance to collect the rich ore while the shift-bosses and other men were on their way out to the shaft. At one time it was a rule that men should leave their dinner-buckets at the office. Some of them came on shift with their food in paper bags so as to avoid going to the office. They were warned not to do so. The next day all of them came with paper bags, and



Combination Mill. Columbia Mt. Mohawk Mine.

Goldfield, Nevada.

called out: "Some one help that son of a gun." In the Little Florence, there was a hoist underground, at the 300-ft. level, and one day the superintendent signalled from a lower level without getting any response, so he climbed up the ladder and found the engineer digging into the bonanza ore in the floor of the level. He was actually getting ready to fire a shot, and had done so previously. In order to escape notice he would time his firing so as to coincide with the blasting in the neighboring stopes, and thus the explosion would pass unheeded. In another mine, the foreman happened to go into an abandoned crosscut and found three carloads of the richest ore lying on a platform ready to be sacked and to be removed through a disused shaft at the far end of the crosscut. Another foreman on another occasion happened the management did not dare to dismiss them. Finally, I may relate the story of the foreman who caught a man loaded with 10 lb. of 'high-grade'; this foreman was notified that there was a watchman paid to do the watching and as he (the foreman) was not a regular watchman he had better attend to his own duties, otherwise the union would have something to say. And thus we come to the root of it all: the subservience of the lessees to the labor union. Why? Because the ore was rich, and the terms of the leases were short, the lessees could not afford to delay the extraction of ore by having trouble with the men: the men knew it, and so stole as much as they could. Everything was sacrificed to a mad rush to make money, the mines were gutted, honesty was swept aside fiercely, the law was made a dead letter.

The rights of property were not respected because the judges who preside over the local courts owed their position to political election, and this made them subservient to the majority of voters, who hap-

*It may be mentioned that in olden days on the high seas the captain's graft was formally recognized and termed 'primage' because he got it first. Nowadays 'primage' is charged in addition to the freight and retained by the ship-owner. The captain does not get it; he no longer participates, he is an employee only. In nearly every industry a similar development can be traced, from open participation to surreptitious graft, and then regulation, which ended all participation in profits.

pen to be mine-workers. Of the mine-owners and operators many have their homes elsewhere, in California, Utah, Colorado, or New York; they do not vote at Goldfield and they exercise scant political influence. Moreover, a large proportion of the lessees who hired the workers in the mines were ordinary miners and laborers themselves, their good fortune was not conceded as due to any superiority of character or talent, therefore the men who were employed thought it reasonable that they should participate in the luck of those by whom they were employed. It was a rough kind of socialism.

The miners stole rich ore, but so did others who might have been supposed to know better. I know of the president of a mining company (not at Goldfield, but in a neighboring district) who used to visit the mine whose operations he supervised and on the occasion of each visit he filled his dress-suit case or valise with specimen ore. Finally, at the end of the fiscal year he told the manager to debit him with $4000. The manager told me that he had kept tally on the little shipments that went from the mine in the president's valise, and he estimated the total value of the ore as being at least $22,000. One of the richest leases at Goldfield was worked by a company organized by a broker; he used to visit the mine in his automobile and take away sacks of ore; it is estimated that he removed $150,000 worth, on which he avoided the payment of the 25% royalty due to the owners of the mine, not to mention the proportion due to the shareholders in his leasing company. Every lease had its sequel of litigation caused by differences of opinion as regards the application of the law of mine and thine. Thus, the Little Florence lessees went 30 ft. over their line and took rich ore from ground not within their lease. In August, 1907, they had to pay the Florence-Goldfield Co. not less than $177,000 in liquidation of a claim for trespass, and were compelled to make a change in the management of the lease operations. When I visited that part of the mine, I found the level barred by a heavy wooden partition placed there to safeguard the rich ore remaining. While at Goldfield I found myself involved in one of these difficulties between lessor and lessee, for I made an affidavit that I found the workings of the Little Florence lease in good shape. According to the terms of the lease, the Little Florence people had to leave five feet of ground under each working level, the idea being that this arch of rock was required to conserve the safety of the workings. I noticed that levels were rather far apart; the first was at 248 ft., the second at 400 ft. from the surface. The question arose whether the ore should be left untouched under an intermediate level. The lease was about to expire (on April 26) and the lessees were gathering all the rich ore that belonged to them. They were also putting the workings in good order, for by their agreement they had to maintain the timbering and hand the mine over in ship-shape condition. I remarked to Mr. Frank Oliver, the manager, that it was a good time to visit a mine when the lease was about to expire, for all the workings appeared so accessible, clean, and safe. The lessees are under compulsion to leave the track in the principal levels, but they may remove piping and tools. Ordinarily they have three months wherein to remove the ore stacked at the surface or in the bins, and to dismantle their equipment. I was in the Little Florence on the morning of April 11. In the afternoon of the same day the Florence-Goldfield Co. asked the District Court for an injunction and cancellation of the Little Florence lease, which was to expire within a couple of weeks, on the ground of improper mining methods and the removal of an arch of rich ore under a level. This was filed on a Saturday after business hours. On a technicality the hearing was deferred to the following Monday morning. Finding that their allegations could not be sustained legally, the lawyers acting for the Florence-Goldfield notified the Little Florence people that they need not appear in court as the case would be dismissed. But before this could be done, the Little Florence company filed a cross-complaint alleging that it was forced to allow the Florence-Goldfield $176,907 that belonged of right to the defendant and to give up part of the lease, or submit to being harassed by the plaintiff so that shipments and operations were hindered. This refers to the old trouble, already mentioned. In the cross-complaint the Little Florence lessees alleged that they had been damaged to the extent of $1,500,000, and asked for this amount of damages. The shares of the Florence-Goldfield dropped at once from $4.27 to $3.95. Such incidents as these, indicating lax notions of property rights among lessees and companies, are not likely to impress the working miner with any marked respect for the possessory claims of either party.

But to understand the extraordinary conditions prevailing at Goldfield last year, it is necessary to refer to the insidious effect of having a stock exchange close to the mines and the participation of owners, lessees, and workmen in the wild speculation arising from discoveries of wonderfully rich ore. The leaders of the labor union were agitators of the worst type, their importance depended upon stirring up strife between the employers and the employees, their opportunity to make money hinged largely on the fluctuations in stocks caused by labor disturbances and the settlement of them. During the strike that was ended in April, 1907, the stock market was worked by the labor-union leaders. They would call a meeting under pretext of settling the strike, and the announcement of this fact would lead to the buying of shares by the general public: they would sell short, and then cover their shorts by open purchases made through their wives; this stimulated more buying; then the counting of votes cast at the meeting of the union would be dragged along so as to afford the time necessary to complete the stock transactions. Thus they see-sawed the market five or six times. This broke the brokers, who had been breaking the public. It was a merciless game of depredation. Never was there a more vivid example of the undermining of character in the presence of wealth: only a few sane men kept their heads in the midst of this scramble for gold, the community as a whole went crazy in the haste to get rich, and threw aside all

the scruples of business morality and even the conventions of financial raseality.

It was amusing to hear the question discussed whether it was proper to leave 5 ft. of ore under an intermediate drift, and whether such an intermediate constituted a level. I found myself no more in sympathy with the lessee who wanted to gut the mine and was willing to precipitate a caving of the workings, than with the lessor who in his greed insisted that ore must be left untouched even though the removal of it could do no harm to the safety of the workings. From the standpoint of legitimate mining it seemed to me that the richness of the ore ought to have little to do with the removal of it, if necessary to hold the workings. The question of removal ought to be decided on its merits, as a problem in practical mining. A well known attorney told me that he had been asked whether the requirement for leaving 10 ft. of ground around the 'sides' of a shaft meant the 'ends' also. He promptly gave instructions to specify the 'ends' in all new leases. A man who risks the safety of his working shaft in order to extract a few tons of rich ore is no miner, and if he is willing to run the risk of injuring a shaft that will revert to the use of, as it already belongs to, the owner of the mine, then he is a thief, just as much as the 'high-grader'.

Thus at every turn the conclusion is reached that the exploitation of ore of unusual richness is subversive of the integrity alike of the man who digs the ore, the lessee whose property it is, and the lessor to whom the royalty is paid. All of them tried to get more than belonged to them; and when they had finished the scramble for their share, the railroad and the smelter levied a toll that was tantamount to highway robbery. There was not much to choose between them all; it was a case of catch as catch can, with the odds in favor of the one who first placed his hands on the ore—the miner himself.

State Geologists.—Representatives of twenty of the State Geological Surveys meeting at Washington on May 13, organized an Association of American State Geologists. Provision was made for an annual meeting and the appointment of various committees for the transaction of the business of the association. H. B. Kümmel of New Jersey was made president; H. F. Bain of Illinois, secretary; and J. H. Pratt of North Carolina was appointed to act with them, forming an executive committee. Messrs. W. B. Clark of Maryland, I. C. White of West Virginia, and J. H. Pratt were appointed a committee to investigate the distribution of documents by the various surveys. J. M. Clarke of New York was appointed to represent the State Geologists on the general committee on nomenclature now being organized, with Samuel Calvin of Iowa, and E. A. Smith of Alabama, as associates.

'Drift' of a diamond-drill may be caused by the use of a core-barrel until it becomes noticeably worn by abrasion. The bit is frequently renewed and is always the same size, while the pipe back of it (the core-barrel) becomes thinner by wear and is apt to sag, thus giving to the bit a slightly divergent course.

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination.

From D. J. S., Seven Troughs, Nevada: Basalt with pyrite.

From W. C. B., Minneapolis, Minn., a felted aggregate of capillary crystals of black tourmaline in quartz.

From Alamos, Mexico: A quartzose metamorphic rock, perhaps a conglomerate-schist; sample too small for precise megascopic determination.

From W. B. H., Placer county, Cal.: No. 1, badly weathered volcanic andesite; No. 2, hornblende schist, little pyrite; No. 3, badly weathered volcanic, andesite-tuff; No. 4, talcose schist with pyrite; No. 5, hornblende-chlorite schist with pyrite; No. 6, fine-grained schist with magnetite.

From C. E. S., Sweetwater, Nevada: No. 1, weathered rhyolite or andesite breccia; No. 2, diabase with veins of epidote; No. 3, weathered porphyry with pyrite; No. 4, quartzite; No. 5, limonite; No. 6, epidote; No. 7, weathered volcanic rock, pyritized; No. 8, limonite and hematite in acid tuff.

From W. McF. S., Outlook, Wash.: No. 1, vesicular lava, probably andesite; No. 2, quartz and chlorite; No. 3, highly weathered acid tuff; No. 4, coarsely vesicular andesite; No. 5, weathered andesite; No. 6, chalcedony; No. 7, hematite and limonite; No. 8, aplite; No. 9, fine-grained mica schist with pyrite; No. 10, weathered tuff containing limonite, kaolin, and manganese oxide.

Received frim J. W. A., Pioche, Nevada: Complex ore containing embolite (or bromyrite), silver bromide, probably with a little chlorine, as the most important constituent occuring in small adamantine yellow-green crystals of waxy texture; also present are malachite, chrysocolla, hematite, limonite, manganese oxide, and a brilliant white crystalline substance in too small quantity for determination.

Material sent by O. H., San Francisco: No. 1, weathered andesite or andesite-tuff with pyrite; No. 2, pyritized andesitic tuff; No. 3, andesite tuff with pyrite changing to limonite; No. 4, highly weathered tuff with limonite; No. 5, weathered vesicular basalt or very basic andesite; No. 6, greatly weathered basalt or basic tuff; No. 7, fresh basalt; No. 8, fine-grained basalt with few vesicles filled with calcite and silica; No. 9, altered andesite; No. 10, andesite; No. 11, andesite; No. 12, acid volcanic brecciated and charged with silica and pyrite; No. 13, pyritized andesite veined with silica.

Steel bands for transmission of power have been successfully introduced by a firm in Charlottenburg, Germany. Such belts are made narrower and lighter than leather or rubber, and hence may be made to run much tighter and greater lengths employed. It is claimed that slipping is reduced so that an efficiency in transmission of 99% is obtained.

UNCONFORMITY AND DEPOSITS.

Written for the MINING AND SCIENTIFIC PRESS
By OTTO RUHL.

The importance of unconformity in the formation of ore deposits has not received adequate attention until very recent years. So impressed were mining engineers and geologists with the idea that most ore deposits containing the useful metals were always accompanied by dynamic movements resulting in great fissures, faults, and fractures in which the ores were deposited from deep-seated sources through an ascending circulation of ground-waters, that other factors entering into the problem have either been overlooked or misinterpreted. A working hypothesis so easily applicable is also likely to be abused. The empirical method, while accurate, is slow, and on this account the engineer and geologist are prone to the error of distorting the field-facts in accordance with theory rather than accepting the facts and then ascribing them to causes in accordance with them. Some such misinterpretation or misapplication of theory has been brought to the notice of every engineer or geologist. It is my intention to point out here how the application of the above theory completely misconstrued the facts in ascribing an origin for the lead and zinc ore deposits of the Missouri-Kansas district.

The area in question consists of rocks of two ages, the prevailing formation being limestone with included beds of nodular chert of Mississippian age. West of the area, as a fringe, occur the lower coal measures of Pennsylvanian age, lapping over and burying the Mississippian rocks. There are numerous 'outliers' of the Pennsylvanian all over the district, lying in eroded depressions of the Mississippian. Every geologist working in this region has noted the existence of this unconformity between the Mississippian and Pennsylvanian, but the importance attached to it has differed. The evidence demonstrates a long period of erosion after the elevation of the Mississippian and before its depression during Pennsylvanian time. This erosion cut the country into hills and valleys and left on the flanks of the hills and in the valleys great quantities of detrital fragments of chert resulting from the breaking down of the more soluble limestone. The effect of weathering was very great, for the limestones were eroded in huge caverns along joint-planes. Many feet of the limestone beds were taken into solution, resulting in a settling of the overlying beds and a concentration of the chert layers or fragments into huge bodies. This solution took place not only during Mississippian times but continued in some measure to the present day. These caverns and underground water-ways resulted in the formation of sink-holes of irregular shape and extent, which were filled with Pennsylvanian deposits during the deposition of those rocks, and constitute today the remaining outliers after erosion has carried away most of the Pennsylvanian. This fact has been one of the most misconstrued of any observed in this region. These outliers have been explained by saying that they were faulted below the Mississippian in conjunction with the faults that must have occurred in order to account for the circulation of ascending waters carrying the ore. This has appeared more plausible when upon a casual examination it was found that many such deposits show disturbance, even faulting within itself and slickensides along the contact with the Mississippian. Detailed work demonstrates that this jumbled condition is entirely due to solution which, occurring at the base of the shales between them and the Mississippian, causes a settling of the upper beds so as to produce movement and slickensides. No faulting of importance can be found anywhere within the district. The faulting can never be traced down into the bedded limestone. Such faulting therefore cannot provide the means for a deep upward circulation of water.

The solution of the limestones and the settling of the beds have crushed and brecciated the nodules and layers of chert below them. We find these breccias in the 'sheet' ore deposits which occur in beds from 150 to 300 ft. below the solid limestone strata of the Mississippian. These chert beds were therefore within the zone of superficial weathering during the period of erosion. These beds, together with the old talus slopes of detrital chert in the valleys and on the flanks of the hills after the laying down of the Pennsylvanian and the re-elevation of the land surface, formed ideal water-channels for the ground-water and also gave the physical requirements for the deposition of the orebodies. The degradation of the Pennsylvanian ensued and the small quantities of the minerals in these rocks were concentrated by downward circulating waters in the underground water-channels at points where the conditions were favorable. During this deposition the broken chert beds were cemented together with secondary chert and minerals. This mass presented a brecciated appearance, the sharp angular pieces of chert being so firmly imbedded in the cementing substance that upon breaking it the new lines of fracture cut across the old chert and the new as though they were a homogeneous rock. These phenomena of brecciation upon superficial examination were mistaken for evidence of faulting but upon detailed study they were found to be in the one case a conglomerate of the detrital chert, and in the second a solution breccia of the beds of chert found below the surface of the floor of the unconformity; they are therefore wholly the result of unconformity and solution.

Here, in three instances, the effects of unconformity were misinterpreted. First, the unconformable beds were mistaken for faulting. Second, the disturbed conditions in the Pennsylvanian resulting from settling of beds that caused small local faults and slickensides induced the belief that faulting must be deep-seated. Third, the brecciated chert beds were mistaken as additional evidence of such faulting. With these basal facts wholly misinterpreted it became easy to explain all the other phenomena in relation to them. Thus grew up the theory that the origin of the lead and zinc ore deposits of Missouri and Kansas involved deep faulting with wide zones of fracturing, an upward circulation from the Cambro-Silurian limestones, whence it was supposed, on account of the magnesia in the deposits,

A Fault. Slickensides on Chert to be Seen on the Left.

FIG. 1.

Disturbed Conditions in Pennsylvanian Shales and Sandstones, Showing Fault With Throw of 8 Ft., at Oronogo. Mining is Being Carried on Below This at the Contact With the Mississippian and Deeper. The Evidence of Solution as a Cause for These Phenomena is Abundant in the Mine Workings.

FIG. 2.

the ores too must have been obtained, a first concentration of the ores and a secondary enrichment. The theory was beautifully worked up, but its basal structure was completely wrong and when thorough investigation was made it was found to be untenable.

The relation of unconformity to ore deposition is very important to the Missouri-Kansas district, for it makes the district, as far as the physical preparation for the deposition of ore is concerned, co-extensive with the unconformity of the Mississippian and Pennsylvanian rocks. It is true that along the entire edge of the Pennsylvanian in Missouri small deposits of lead and zinc have been found, but nowhere have developments been carried to the extent they have in Newton, Lawrence, and Jasper counties. Late developments in Oklahoma, where the coal measures skirt the Mississippian, have shown a new field for mining. The limitation of the region appears to be therefore confined entirely to the zone in which the degradation of the Pennsylvanian has been sufficient to furnish a workable deposit of ore, and the relations existing between oxidizing and reducing solutions were such as to form this deposit in the favorable places along the unconformity between the Pennsylvanian and Mississippian rocks. The final degradation of the carbonaceous shales of the Pennsylvanian tends constantly to diminish the amount of reducing solutions, and it is a noteworthy fact that the heavier deposits of ore occur in close relation to such beds. As prospecting recedes from the Pennsylvanian the ore deposits become lean and less important unless protected by an 'outlier.' A limitation, which has no reference to unconformity, may be found however in the extent to which the Pennsylvanian rocks have been impregnated with the requisite quantity of ore to furnish deposits in commercially important orebodies. This is a problem for the chemist and geologist to work out together.

If unconformity, erosion, and solution have been the agencies preparing the physical means for ore deposition in so large a field as this, is it not possible that more detailed work in other regions may reveal some such relation there? It may be that many of the phenomena credited to faulting in other districts where the ores are plainly the result of a concentration from circulating ground-water are but the effects of unconformity, erosion, and solution. Indeed, it is not improbable that the importance of unconformity in its relation to the formation of orebodies, especially if the superimposed beds are sediments resulting from a degradation of igneous rocks or sedimentary rocks immediately derived from them, will become a greater factor in the work of the engineer and geologist in the development of new mining districts.

In conclusion, the Missouri-Kansas district furnishes a striking example where even the best trained and experienced engineers and geologists for a long time mistook the effects of unconformity, erosion, and solution, and should teach the lesson that mere disturbed conditions in superficial strata, even when attended with slickensides and breccia, are not incontrovertible evidence of orogenic movements involving faulting to great depths.

A DERELICT.

The Nevada gold country has exerted its allurements in the past, and has witnessed its sacrifices, as appears from the accompanying illustration of a quaint mill for the reduction of gold ores, still standing abandoned in the desert some 45 miles

south of Goldfield in the extreme southern point of Esmeralda county. By the manufacturer's nameplate and other evidences, it appears to be a derelict of expectations wrecked at least 20 years ago. Inside the rocking mortar were two cast-iron rollers, 12 in. diam., the evident intention being to consume as much power as possible with the lowest result, in a place where power-generation would at that time have made the most economical crusher extremely costly to operate. It is a mute reminder of the credulity of man, and of his tendency to follow the advice of the charlatan in mining.

Alabama, although not recognized as a gold and silver producing State, has contributed her small share to the world's precious metals. In the 107 years since 1800, she has produced, according to the U. S. Geological Survey, a total of $760,470. This amount represents an annual production of $7107, but only once in the 24 years from 1880 to 1903 did the recorded production reach this mark. However, in the three following years the amount produced has been:

	1904.	1905.	1906.
Gold	$29,300	$41,530	$24,921
Silver	116	203	83
Total	$29,416	$41,733	$25,004

This increase is due to the renewed activity in the Hog Mountain mine, in Tallapoosa county. In addition to the above mine, those at Gold Ridge, in Randolph county; at Clear Creek, in Cleburne county; at Pinetucky, in Perry county; and the Tallapoosa mine, four miles southeast of Hog Mtn., have contributed to the total production. The mines at Pinetucky were probably worked early in the last century. Along the banks of a small stream are found extensive dumps, apparently old placer washings, in which trees at least 100 years old are growing.

ALPINE AND AMERICAN TUNNEL RECORDS.

The Rieken tunnel headings met on March 30. This tunnel is in the Canton St. Gallen, in northeastern Switzerland, and extends from Uznach to Wattwyl. It shortens the north-south railway routes in eastern Switzerland, though if either the Splügen or the Greina tunnel project goes through, the Ricken will serve mainly local needs. It is 28,221 ft. long between portals. It was begun about the end of 1903, and progressed steadily, with occasional trouble from firedamp but without excessive difficulty until March, 1907, when, the headings being 93% through, a strong flow of firedamp was tapped in both north and south headings. The gas, which took fire, stopped all work for some months, but in July the full-section enlargement and lining operations were resumed, with the use of safety lamps. In October the fire was out and the flow of gas small; the temperature having gone down, work was resumed at the south heading with safety lamps, and since then the work has progressed without serious interruption, until at the end of February, 1908, the headings were only 531 ft. apart. The south heading was advanced this entire distance during the first 30 days of March, making a new record for hand-drilled tunnel progress.

It is interesting to note here a comparison between American and Alpine records for rock tunneling. A list of the more notable performances is given in *Engineering News*, April 2, 1908, from which the above table is compiled.

From a study of the data it is evident that the Alpine records are far ahead of the American. The Gunnison record of 449 ft. with machine drilling is 82 ft. less than the new record of hand-drilled work in the Rieken tunnel. European tunnel constructors universally prefer the bottom heading method, while in America the top heading is always used. Is this difference responsible, says the *Engineering News*, for the difference in maximum progress rates? Or is sufficient explanation found in the greater length of the principal Alpine tunnels, and the resulting economies achieved by installing more perfect plants and arranging a more thorough organization?

ROCK TUNNELING RECORDS.

Name.	Place.	Date.	Maximum progress of a single heading. Ft. per mo.	Method of drilling.	Remarks.
Mt. Cenis	Alps	1857–1870	297	Machine	
Hoosac	Massachusetts	1865–1873	184	Machine	
Sutro	Nevada	1869–1877	417		Probably in one heading
Nesquehoning	Pennsylvania	1871	165	Machine	
St. Gothard	Alps	1872–1881	436		Averaged 343 ft. per month for one year
Arlberg, east heading	"	1880–1883	637	Ferroux percussion	
" west heading	"	"	641	Brandt rotary	
Stampede	Washington	1897-1900	301		Northern Pacific Railroad
Kellogg	Idaho	1898	345	Machine	Bunker Hill & Sullivan mine
Albula	Alps	1900–1902	607	Brandt rotary	
Bosruck	Austrian Alps	1902–1905	546		
Simplon	Alps	1900–1905	685½	Machine	World's record
Tauern	Austria	1902–1907	548		
Ricken	Switzerland	1903–1908	531	Hand	World's record for hand-drilling
Raton	Colorado	1907	412	Pneumatic augers	A. T. & S. F. Railway
Gunnison	"	1908	449	Machine	

'The Strength of Chain Links' is the title of Bulletin No. 18, recently issued by the University of Illinois Engineering Experiment Station. The authors, C. A. Goodenough and L. E. Moore, have deduced, by theoretical considerations, rational formulas for the strength of chains, and have experimentally established the validity of such formulas. The following conclusions, based upon results of the investigations are presented. "The introduction of a stud in the link equalizes the stresses throughout the link, reduces the maximum tensile stresses about 20%, and reduces the excessive compressive stress at the end of the link about 50%. The stud-link chain of equal dimensions will, within the elastic limit, bear from 20 to 25% more load than the open-link chain. The ultimate strength of the stud-link chain is, however, probably less than that of the open-link chain. The following formulas are applicable to chains of the usual form: $P = 0.4d^2S$ for open links; $P = 0.5d^2S$ for stud links; in which P is the safe load; d, the diameter of the stock; and S, the maximum permissible tensile stress. In the formulas given by leading authorities on machine design, the maximum stress to which the link is subjected seems to be underestimated."

O'HARA POCKET MINE.

Written for the MINING AND SCIENTIFIC PRESS
By An Occasional Contributor.

The O'Hara mine is situated in Tuolumne county, a short distance north of Sonora, in what is called the 'pocket' region of California, extending from Sonora northward into Calaveras county, thus including Columbia and Bald mountains. From this zone many millions of dollars worth of gold have been taken in the form of pockets and coarse placer gold and nuggets undoubtedly derived from the erosion of 'pocket' lodes, and it has yielded a large proportion of the finest crystallized gold specimens and gold-tellurium minerals found in the State.

The bonanza of the O'Hara mine occurs in slate of the Calaveras formation near its contact with crystalline limestone. The mine is entered by a very flat incline running west of north, following the dip of a flat dike or sheet of light greenish porphyry; this cuts both limestone and slate, and constitutes the vein. At intervals, certain nearly vertical partings or crossings are found, often no thicker than a knife-blade, which cut obliquely across the shaft or incline. Pockets are expected only at the intersection of one or more of these crossings with the porphyry in a particular narrow belt of black slate, which is probably carbonaceous, and they are also associated with the presence of another intrusive, locally called 'granite,' but which is very fine-grained and is probably an older silicified porphyry. In the porphyry sheet one or more thin seams sometimes occur, approximately parallel with its general direction. When pockets occur, these seams widen out to several inches and contain gold and tellurium minerals in hard white quartz. The richest portions of the bonanza, however, were flat rough masses or irregular slabs of almost solid gold with more or less adhering telluride. Gold sometimes extends also into the mass of the porphyry itself. Near these pockets the flat sheet of porphyry may widen out and spurs from it sometimes break into the slate, which is locally shattered and more or less veined with quartz. The porphyry, the 'granite', and the black slate are more or less impregnated with finely disseminated pyrite, which itself contains but little gold.

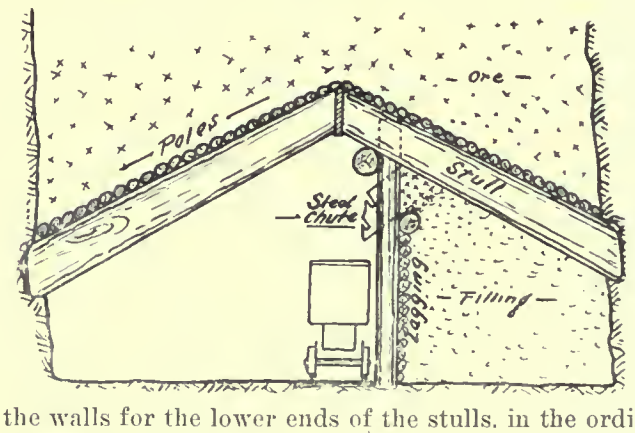
As the gold occurs in and below, but seemingly not above, the porphyry sheet, it is probable that the thin crossings which are partly filled with quartz and some carbonate of lime, have been the channels through which mineralizing solutions have risen until stopped by this capping and have spread and deposited the gold and tellurium mineral. The free gold of the O'Hara pocket mine is fully 900 fine, making the ratio of gold to silver approximately 9:1; and a similar ratio has been found in several other pocket mines in the vicinity. In the telluride of the recent bonanza, however, there is a large proportion of silver, and the ratio of gold to silver is said to be about 1:2½. In other mines of the district there is a wide variation in this respect; some of the tellurium minerals are said to contain silver exclusively while others are practically free from precious metal or at most enclose a little free gold. The gold obtained from the Bonanza mine, in the same district, is said to have run from 825 to 875 fine, but was probably lowered in fineness by the presence of tellurides containing silver.

Little information can be obtained as to the exact value of the recent find, but at least $150,000, and probably double that amount, has been extracted. In addition to this, all the rock in the immediate vicinity of the bonanza will be milled to secure any gold that may occur in the quartz stringers or porphyry.

The somewhat similar mode of occurrence of pockets in the Bonanza mine, situated a short distance away from the O'Hara and in the outskirts of the town of Sonora, has been described in the 8th, 10th, and 12th reports of the State Mineralogist, pages 652, 736, and 299, respectively. The general geology of the district has been mapped and described by the U. S. Geological Survey in the 'Big Trees' and 'Sonora' sheets, as it lies on the boundary of these two tracts.

The large size of many of the masses of gold taken from the O'Hara, the Bonanza, and other mines of the district, amply accounts for the largest of the numerous nuggets found in the adjacent placers, without requiring any theory involving a resolution of the gold in the gravels. The contiguous crystalline limestone, forming the bed of the creeks worked by the pioneers, was most irregularly eroded so as to afford ideal natural riffles which caught any gold resulting from the erosion of the pocket veins before it traveled far enough to suffer much abrasion. How profitable the working of this limestone bedrock must have been, is evident from the amount exposed by the old workings in and around Brown's Flat.

Saddle-back stulls in use in the mines of Kalgoorlie are shown in the accompanying figure. The principle is very simple. Two stulls are cut to fit like the rafters of a roof, with a face-plate between the ends at the angle where they meet. Hitches are cut in



the walls for the lower ends of the stulls, in the ordinary way. In effect, the saddle-back stull is a toggle-joint, and when loaded with waste above the lagging, the load instead of being entirely transverse is resolved into components and the stull acts as a compression member and transmits a thrust against the walls. Thus, not only may wide spaces be stulled, but stulls of smaller sectional area may be employed than would be required for equivalent loads when the timbers were not thus framed.

MINE REPORTS.

UNITED STATES SMELTING, REFINING & MINING CO., BOSTON.

The second annual report of the United States Smelting, Refining & Mining Co. covers the year ending December 31, 1907, for which period the profits amounted to $2,070,213, and dividends of $2,768,580 were paid. Undistributed surplus on December 31 stood at $557,003, against $1,990,572 on December 31, 1906. The metals contained in bullion produced in 1907, including metals from custom ores, but not including the production in Mexico, were as follows:

Copper	38,518,378 lb.
Lead	53,617,324 lb.
Silver	6,739,269 oz.
Gold	235,882 oz.

The income account is as follows:

Metals in bullion produced in 1907		$18,408,654
Deduct selling, commission, and shipping exp.		161,071
Balance		18,247,583
Excess of ores at beginning of year over end of year on hand and in transit		444,646
Balance		17,802,937
Miscellaneous earnings from ore sales, royalties, rentals, etc.		179,156
Total		17,982,094
Cost of production, including custom ores and matte purchased		16,154,513
Net		1,827,580
Miscellaneous revenue		558,959
Total net		2,386,540
Depreciation and reserve	$120,009	
Administration and legal expenses	166,317	
Interest on 6% debentures U. S. M. Co.	30,000	316,326
Balance of profits for year		2,070,213
Previous surplus		1,990,572
Total		4,060,786
Less depreciation in metals unsold at end of year, including metals and ore in process		733,255
Balance		3,327,531
Dividends on minority stock of subsidiary companies		1,947
Dividends on U. S. Smelting preferred (7%)		1,672,348
Dividends on United States Smelting common		1,096,232
Undistributed surplus, December 31, 1907		557,003

The copper produced during the year was sold at an average of 18.83c. per lb., lead at 5.20c., silver at 65.20c. per oz., and gold at $20.56. The ore produced from the Centennial-Eureka, Mammoth, and United States mining properties was 406,748 tons, of which the values of the metal contents were in the proportion of 56% copper, 4% lead, 18% silver, and 22% gold. At the Mammoth plant in California there have been completed, during the past year, the enlargement of the smelter; the construction of the converting plant; the construction of the railroad to connect the mine and the smelter, and the construction of the railroad to connect the Quartz Hill mines with the Southern Pacific railway. These are now (April, 1908) all in operation, and will nearly double the smelting capacity at Mammoth, and permit the converting of Mammoth matte into copper bullion at that plant in place of shipping the matte to Utah to be converted as heretofore. Another important advantage is that with the increased smelting capacity, and a converting plant at Mammoth, the Centennial Eureka mine in Utah will not hereafter be entirely dependent on the Utah smelter. Some ores from Centennial-Eureka can now be shipped to the Mammoth smelter in case of necessity.

At the smelting plant in Utah many additions and experiments have been made with a view to avoiding damage to the surrounding farms by smelter smoke. On a recent showing in the United States Circuit Court as to what has been accompliished in this direction, the Court modified its decision so as to permit the operation of the lead smelter. Preparations are now being made to resume at the Utah plant the smelting of custom ores and ores from Centennial-Eureka and Bingham mines.

Experiments have been in progress on a process for neutralizing the sulphuric acid in the smoke so as to permit the passing through a bag-house of all the smoke from the various smelting operations. The company's research chemist, C. B. Sprague, developed a process that has made this operation practical.

From the Bingham properties 97,321 tons were extracted during the year; 194,016 tons was shipped from the Centennial Eureka, and the Mammoth mines produced 201,123. The total amount of charge handled during the year was 659,306 tons. The company has been increasing plant and extending the scope of its operations widely and rapidly. The new plant includes the copper smelter at Chrome, equipment for the Richmond-Eureka mine, and the Loreto and Guerrero mills at Pachuca. As a shareholder it is also interested in the new smelter of the Peruvian Mining & Smelting Co. The United States Mining Co. owns either the whole or a majority of the stocks of the United States Smelting Co., Centennial-Eureka Mining Co., Mammoth Copper Mining Co., United States Stores Co., United States Lime Co., United States Metals Refining Co. It also owns one-half of the stock of the International Metals Selling Co. and a majority of the stock and bonds of the Niagara Mining & Smelting Co. It owns all the preferred stock and a majority of the common stock of the American Exploration Co., and has acquired during the year additional holdings in the Richmond-Eureka Mining Co. In addition to the nine-tenths of the stock of the Real del Monte Mining Co. already owned, the company acquired during the year all the remaining capital stock of that company, namely, 15,984 shares, which were received in exchange for an equal number of shares of preferred stock of the United States Smelting, Refining & Mining Co. Through this ownership it becomes the holder of over 99% of the stock of the Compañia de Real del Monte y Pachuca, in Mexico. The total number of preferred stockholders is 5104, and of common stockholders 1405 at this date. There are outstanding 6% debentures of the United States Mining Co., maturing in 1909, amounting to $500,000.

RAND MINES, LTD., TRANSVAAL.

The report of the directors of the Rand Mines, Ltd., for the year 1907, at the thirteenth annual meeting in London, presents the following statement of accounts:

Cash and cash assets on hand, end of 1906		£757,244 6 2
Net profit earned for year under review		675,082 8 0
Total		£1,432,326 14 2
Which has been dealt with as follows:		
Investment accounts—		
Net increase for year	£50,293 16 6	
Debentures repaid or purchased	121,150 0 0	
		£171,443 16 6
Dividends No. 8 and 9		583,685 14 0
Balance, cash and cash assets on hand, after allowing for all liabilities excepting debentures		677,197 3 8
		£1,432,326 14 2

The profit and loss account gives full details of the profit for the year. The amount received for dividends on shareholdings again shows a substantial increase for the year, being £87,404 7s. 3d. more than for the year 1906. The more important changes in investments during the year consist in the purchase of 15,283 £1 shares in the Durban Roodepoort Deep, Ltd.; 8200 £1 shares in the Paarl Central G. M. & Exploration Co., Ltd.; 5875 £1 shares of the Simmer & Jack West, Ltd., were exchanged for 7050 £1 shares of the Jupiter G. M. Co., Ltd., on the amalgamation of those companies. Sundry miscellaneous shares were acquired, at a cost of £38,358, and 4338 £1 shares of the Robinson Central Deep, Ltd., were sold.

During the past year the company took advantage of its rights under the debenture conditions to purchase £37,800 of the outstanding debentures, which have been cancelled, together with the £83,350 redeemed at the commencement of last year. The total reduction in the issue for the year

is thus seen to have been £121,150, and the balance outstanding on December 31 was £378,850. A further annual installment of £83,350 was drawn on December 3, 1907, for redemption on January 1, 1908. Dividends amounting to 130%, or 6s. 6d. per share, have been paid during the year. The amount distributed was £583,685 14s. It will be seen that the amount paid in dividends aggregates £3,239,735 12s.

The general manager's report contains full particulars of the operations of the Subsidiary Companies and information respecting other companies in which the Rand Mines, Ltd., holds an interest. The Subsidiary Companies show increased working profits over the previous year amounting to £375,115 4s. 4d. The crushing duty per stamp has been increased to an average of 6.181 tons per day, and the average working costs show a reduction of 1s. 3.625d. per ton. This satisfactory result has been accomplished chiefly by the tube-mill installations which have been in full operation during the year. It should be noted that the average actual extraction was 94.858% for the year, as compared with 93.858% for the year 1906, while the average value of residues has fallen to 0.461 dwt. per ton, as against 0.531 dwt. per ton for the previous year.

In May last a strike took place among the miners of the Witwatersrand, and most of the Subsidiary Companies of the group were affected. The strenuous efforts made by the managers and the loyal co-operation of their staffs enabled the companies to carry on operations without interruption, though on a slightly curtailed basis. But for this the results of the year would have shown an even greater improvement. Three of the Subsidiary Companies have in hand additions to their plants—the Nourse Mines, Ltd., proposes to add two tube-mills to its 80-stamp mill, together with additional cyanide plant for the treatment of accumulated slimes: the Ferreira Deep, Ltd., has erected and shortly will be running a further 40 stamps, making in all 160 stamps, together with tube-mills and other plant; the Durban Roodepoort Deep, Ltd., in view of the encouraging developments from its new shaft, has decided to erect a further 40 stamps and additional cyanide plant, which will be running toward the end of the year. The Langlaagte Deep, Ltd., will shortly pay its first dividend, and may be expected to contribute regularly toward the company's income. All the producing Subsidiary Companies of the group, with the exception of the Durban Roodepoort Deep, Ltd., are thus paying dividends. As regards the last-named company, it is expected to enter the dividend-paying stage by the end of 1909. The repatriation of a number of Chinese coolies employed by various Subsidiary Companies has proceeded during the year, and will continue during the next two years as the contracts of service of the laborers expire. The replacing of these laborers by natives has received close attention, and thus far an adequate supply of native laborers has been obtained; it is, however, impossible at the present time to state definitely whether the efforts being made will be successful in permanently replacing the 13,500 Chinese laborers imported by the mines of the group. Assuming an adequate supply of native labor to be obtained, it is anticipated that the Subsidiary Companies of the group will show enhanced profits during the year 1908. Owing to the exhaustion of working capital, the South Nourse, Ltd., was compelled to discontinue its development operations at the close of the year.

COMMERCIAL PARAGRAPHS.

THE AMERICAN SPIRAL PIPE WORKS have moved their New York office to the Hudson Terminal Bdg., 50 Church street. Mr. F. B. Sanborn is in charge.

THE FORT WAYNE ELECTRIC WORKS, Fort Wayne, Indiana, have issued 'Instruction Book' No. 3032, describing their alternating current series arc-lighting system.

THE BRODERICK & BASCOM ROPE CO., St. Louis, has issued a handsomely printed and illustrated pamphlet which they have named the 'Underground Haulage Catalogue.' It describes their system of wire rope haulage and gives some comparative costs for mule and wire-rope haulage. The catalogue will be sent, free of charge, to any address.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

DEED FOR MINING CLAIM—FAILING TO CONVEY EXTRA-LATERAL RIGHT.

A patent for the Massachusetts Hill Quartz Mine described certain surface ground containing about 50 acres as designated in the official survey; also a certain number of lineal feet of said mine, vein, ledge, or deposit for the length hereinbefore described throughout its entire depth, although it might enter the land adjoining; also other veins throughout their entire depths, the tops or apexes of which lay within the exterior lines of said survey within the end lines. The Massachusetts Hill Quartz Mine was a consolidation of several smaller claims; one was known as the 'Ford & Reilly' and another as the 'Stockbridge.' Thereafter the patentee conveyed to other parties a part of said mine described by the deed thus: "To that portion of said mining claim which lies east of the west bank of Wolf creek and west of the east line of said survey, being all that portion of said ground and mining claim embraced within said patent, and the survey upon which the same is founded, which lies outside of or easterly from, that part of said Massachusetts Hill mine, known as the Ford & Reilly location," etc. The deed also provided that it embraced only that portion of said mine, as surveyed and included in said patent, which was included in the Ford & Reilly survey, outside of and easterly from the actual lines and boundaries of the Ford & Reilly square location, and should not include any portion of said Massachusetts Hill mine, which was heretofore known as the 'Stockbridge Location.' The deed also conveyed all title, interest, mining right, property, and possession in or to said premises. The land actually conveyed was a small strip of less than one acre out of the original claim. In a subsequent action brought by the owner of the strip of ground so conveyed by said deed against the then owner of such Massachusetts Hill mine for the value of gold-bearing rock taken by the defendant, beneath and within the surface limits of the tract so conveyed by said deed, it was held that the defendant had no right to work the Massachusetts Hill vein where it lay beneath the surface of the land so conveyed to the plaintiff; that by the peculiar wording of the deed the grantor of the remaining tract had no right to follow the vein where it extended beneath the surface of the land conveyed; in other words, the original grantor and his successors in interest were estopped from subsequently claiming extra-lateral rights to a vein the apex of which was within his surface description.

Riley *v.* North Star Mining Co., (Cal.) 93 Pac., Dec., '07.

LOCATION OF MINE—NOTICE.

The United States Statutes providing that location of mining claims shall be distinctly marked on the ground, so that the boundaries can be readily traced, and the location notice filed, and shall contain a description of the property by which it can be identified, was held to be mandatory, and must be complied with in order to secure a valid location.

Ware *v.* White, (Ark.) 108 Southwest. 831, Jan., '08.

REMOVAL OF MINERALS—INJURY TO SURFACE—MEASURE OF DAMAGES.

Where the surface soil is injured by the removal of mineral without leaving the proper support, the damages must be based on the injury to the surface and improvements caused by such mining; and that such damages would be the difference between the value of the land immediately before the commencement of the mining, and such value immediately after the mineral was removed; and that in determining such difference the damage to improvements might also be considered.

Collins *v.* Gleason Coal Co., (Iowa) 115 Northwest. 497, March, '08.

Editorial.

IMPROVEMENT of trails in Alaska is work well worthy of commendation. The Alaska Road Commission is to improve the main winter trail from Valdez into the interior and to construct new roads to mining camps in need of such links with the outer world. Many mining districts would gain more from good roads open to general traffic than from a single railroad controlling transportation at the sweet will of one corporation.

DURING the seven months since the October panic froze the frothy current of business, the tide of immigration has been less strong than the outward flow of population. Official records show that 467,000 work-people have left our shores, as against 337,000 entering the country, so that there has been a loss of 130,000. Even of the 337,000 no less than 117,000 came in November, before the effect of the panic was fully felt in Europe. A similar result followed the panic of 1893, although immigration was never before less than emigration.

A CRITIC reminds us that the Tennessee Coal & Iron Company, to which we referred last week, is merged into the United States Steel Corporation. This fact does not affect the point of our argument, which is that the placing of a certain order for rails only remotely affecting the general public, was proclaimed by the press as an example of financial patriotism, so to speak. The gist of it is that some money-interests, no matter which, sought to mislead the public and to manufacture sentiment. Sound business can not be built on so tenuous a commodity. Commerce is exchange of goods, not trading in hope and faith, although faith and hope are most useful in their way. The extent of the purpose to deceive appears with conclusiveness from the circumstance, of which our critic informs us, that the order of the Illinois Central Railroad for $1,456,000 worth of steel rails was actually placed last November. That looks as if the rails were seriously needed, and eliminates magnanimity and altruism as motives in any degree for the action of the railroad. The dispatches were intended to create a false impression; the effort was to manufacture good times, and the factory seems to have been situated on Wall Street.

ON ANOTHER page we take pleasure in publishing nearly the whole of a paper by Mr. Thomas H. Leggett, recently read before the American Institute of Mining Engineers. Mr. Leggett gives a most interesting summary of recent progress in the mining industry of the Transvaal. Incidentally he refers to remarks made by "one of the leading mining journals of the United States" in regard to over-capitalization of South African mines. Our ineradicable

modesty would prevent us from supposing that Mr. Leggett was referring to this journal, were it not for the fact that our pages were devoted to a discussion of this subject not long ago. He suggests very properly that the stock-market rating of shares is not the same as the nominal capitalization at the time of company organization and that this fact may have led to a confusion of ideas. But there really has been less confusion than might be supposed, for the public bought the shares on the market at three or four times their par value and so became the victims of over-capitalization. In many cases the stock was issued at a premium of 100 per cent or more, that is, £1 shares were offered to the public at £2 or more, so that any reference to the nominal capital is likely to be deceptive. The Ferreira may pay 300 per cent dividends in one year, but as the £1 shares sold at £25 in 1905 the dividend of £3 represents only 12 per cent; as the life of this mine is estimated at 5 years, 12 per cent is a wholly inadequate return from the investor's standpoint. As a matter of fact, while the financiers and promoters went in on the ground floor and obtained the shares at a price that ensured a safe and most attractive investment, the shares of the principal mines were offered to the public at a premium so large and were then boosted to a price so high that the majority of investors found themselves unlucky speculators, that is, they bought for the sake of the regular interest on the money they put into Rand shares and, though many of them lived to see the prices kited, they did not sell but held to their stock only to find in the end that they had an investment which, after making allowance for redemption of capital, gave them 3 or 4 per cent, plus anxiety. For this over-estimation the better class of mining engineers were not responsible, and when retained by investors they gave them sound advice, which was often set aside in favor of more optimistic and less responsible counsellors.

WHETHER Mr. Hammond will be elected Vice-President, whether, indeed, he will even be nominated, is a matter outside the scope of our comment, for this journal can have nothing to do with party politics. But the incident will prove interesting to many members of the profession in which Mr. Hammond was trained, and it prompts one or two observations. In the first place, the idea of a man without experience in politics or legislation, though unusually capable as a financial diplomat, becoming the presiding officer of the United States Senate and a possible successor to the President in case of a fatality, will seem strange to a European. And yet such is the marvellous adaptability of the American character that men with less preparation have filled these offices with credit to themselves and to the country. But to us the most interesting feature is the practical assertion that a successful mining engineer is fit for any post, however high and however responsible. We like that. Time was when the mining engineer, especially in England, was regarded as a nondescript adventurer with a penchant for mineralogy: even now he yields social precedence to the Army, the Navy, and the Reserve Forces, to the Church, to the landowners, and what not besides. In France, it is true, the graduate from the École des Mines has an assured position, only second to his friends in the Army, but that is due to the fact that the École des Mines is recruited largely from well-born families. The profession itself has no special status. In America, it is altogether different. A mining engineer, like any other educated, efficient, and respectable man, need yield precedence to no one—save his wife. By reason of that equality of opportunity which is at once the glory and the strength of the American ideal, a mining engineer or any other professional man in good standing is eligible for any office from Deputy Mineral Surveyor to President of the United States. It is the emphasis placed on this fact that makes Mr. Hammond's candidacy of particular interest. As a demonstration of the democratic character of American institutions, it is worth a good deal. And why not? Doctors have proved fairly good Brigadier Generals, editors have commanded regiments creditably, publishers have proved that diplomats can be made at least as quickly as they are born, and lawyers unnumbered have taken the cares of empire without the smallest hesitation. What is the matter with the mining engineer? He's all right.

Railroad Control.

MOST of the people on the Pacific Coast will have heard with regret that Mr. George Gould has made a deal with Mr. E. H. Harriman whereby the Western Pacific railroad is to be operated under a gentleman's agreement obviating excessive competition, or, in plain English, a practical conspiracy to maintain excessive rates. Gould seems to have burned his fingers in some other railroad enterprises in the East and finding him in financial straits, Harriman has sand-bagged him into a receptive mood. Thus another hope of getting out of the grip of the Southern Pacific railroad is shattered; California, Nevada, and Arizona remain under the industrial domination of Harriman, a gentleman-pirate. We are aware that Gould offered Western Pacific bonds for sale on this Coast and apparently obtained scant support; which was a great pity. Unification should make for better and cheaper transportation facilities. We know that in effect the dominance of the one-man power has not given advantage in either quality or cost of service to the public, while it has given an enormous stimulus to stock-gambling. The two portions of the country where the railroad systems are under monopolistic control are precisely those where the rates are highest. In the New England States, where the New York, New Haven & Hartford interests dominate all lines from Hudson river points eastward, together with their network of feeders, the average freight rate per ton mile is 1.20 cent, which is the highest average rate existing in any group of States in the Union. Next to New England stands the Pacific Coast group with a rate of 1.13 cent per ton mile. It may look as if the Southern Pacific system were the more merciful of the two, but in fact the greater average length of haul runs up the average receipt per ton to $2.337, while the toll

taken in New England, where the population is large and the local short-haul freight movement is relatively large, amounts to $1.047 per ton. The Middle States possess the largest mileage of railroads unconsolidated with the great monopolistic systems, and exactly in that territory do the lowest rates obtain, being 0.65 cent per ton mile, or 71.8 cents per ton of goods moved. These figures are eloquent. The people of New England failed to sustain the New York & New England and the Boston & Albany as independent systems, and they are now paying the penalty. The people of the Pacific Coast likewise failed to sustain the Santa Fé system, and now they fail to sustain the Western Pacific. Supineness is a characteristic of democracies up to a certain point. It invites the over-reaching of powerful interests in an effort to absorb the earnings of the people. This has gone on in America until apparently we are drifting to a condition of railroad control under which three or four unscrupulous men will pull the strings for all the mail lines of transport, and the only consolation is that when they finally do win a complete control, they will lose it; for the American people will then have their eyes opened and will insist on Government management of the monopoly.

Technical Education.

IN OUR last issue we published a letter from Mr. Thomas T. Read, now professor of mining in the Imperial University of Tientsin. He discusses the education of mining engineers. It is well to ventilate the subject occasionally. Last year we ventured to suggest that each chair of mining and metallurgy should have two professors, one of whom would be lecturing while the other was gathering ammunition and inspiration in the field, that is, acquiring the first-hand knowledge without which lectures tend to become a hollow mockery. Not that we depreciate theory in order to extol what is called practical knowledge; that were to play to an ignorant gallery, for effective education must include both the study of theory and the study of practice, so that the one may be properly understood and the other intelligently applied. A teacher must have experience, and that experience, in mining or metallurgy, for example, he can get either by professional work or by close association with those doing such work. He must leave the lecture-room and go into the mine and mill. He must get alongside facts.

Discussion on this, or any other, subject is futile unless we can agree in defining the terms we use. The word 'education' expresses the divergent ideals of different people. As the dictionary defines it, education is the systematic development and cultivation of the mind, it means the drawing out of the best that is in a man and the directing of his intellectual powers to useful purposes. But here many of us part company, for what are 'useful purposes'? Shall it be our aim to turn out a highly specialized money-making human mechanism, able to earn a salary and gain great wealth at an early age? It is fair to say that some such description would fit the beau ideal of many a school of mines today. Even those who are not devoted to a crass materialism will state with the air of a great discovery that the ideal education is the one that gives the student the training best fitted to his individual development. Another idea is that the cultivation of the student's mental powers should be such as to conduce to his maximum happiness in the scheme of creation wherein he finds himself placed by no choice of his own. And it may be argued that happiness is not won by technical knowledge nor by the financial reward accruing therefrom, although knowledge and money are largely contributory to human happiness. But what is 'happiness'? Unfortunately most men only find out what is most worth having in life when life itself is near its close; a large majority chase rainbows, others stretch eager hands for Dead Sea apples that when caught are as sawdust in the mouth; not many see the fruition of their labors before the sun sets.

The engineer does not get as much out of life as he ought, because his education is faulty. He must be something of a philosopher or he remains a good deal of a fool. Man does not live by bread alone. To bring up a young fellow with the idea that the large salaries paid by the big corporations represent the laurel wreath of honorable effort is to incite children looking for food to an eager search for pebbles. The lack of money and the excess of it are alike destructive of the best that is in man; our hope should be to train a youth so that he can gain a livelihood, without looking to money as the sole purpose of his education, which should in the main be directed toward fitting him for his duties as a progressive member of the community. The man must not be sacrificed to the specialist. Engineers do not play the important part as citizens that they should, considering the effort to give them a special training, their contact with facts, their control of natural resources, their leadership in modern industry. Engineering education is not fruitful; there is too much ploughing of infertile sands; the furrow remains barren. We get assayers instead of scholars; we get samplers instead of thinkers. The old cry of unpractical dreamers being graduated from the technical colleges is no longer true; we now get uncultured and unhappy job-chasers.

Is it worth while, either from the standpoint of the individual or of the community? After all, it is the community that supports the educational establishments, whether it be directly by State endowment or by personal benefactions, and the community has a right to ask for a product conducive to enlightened progress. The individual may want to be trained as an efficient money-maker and he is entitled to receive the equipment necessary to give him a chance in the competition of life, but after that has been accorded it is well that those in authority should insist on a preparation which while conducing to his own future happiness shall also contribute to his usefulness as a citizen. The best product of any university today is a good citizen, that is, a man able and willing to do his duty as a unit in the Home, the City, the State, and the Nation. Any man able so to do is adapted to his environment and is fitted to live happily in this struggle for existence.

Personal.

W. H. Weed is at Nelson, B. C.

Bradford H. Locke is at Los Angeles.

F. L. Bosqui has returned from Goldfield.

Donald F. Campbell is on his way to London.

R. C. Shaw has returned to San José, in Costa Rica.

Robert T. Hill is expected in San Francisco shortly.

Grant H. Smith of Salt Lake is on a visit to this city.

R. H. Channing is in New York, from Cerro de Pasco.

W. J. Scrutton has returned to London from Venezuela.

F. L. Morris has gone to Hermosillo, in Sonora, Mexico.

W. H. Linney, of Spokane, was in San Francisco this week.

S. H. Pitkin, of the Wellman-Seaver-Morgan Co., is at Denver.

Robert Schorr has returned to San Francisco from Europe.

James Hoatson has returned to Calumet, Michigan, from Europe.

Frank H. Probert is examining mines near Patagonia, in Arizona.

R. Gilman Brown has returned to London from South America.

R. H. Toll is examining mines in Clear Creek county, Colorado.

S. F. Emmons will spend the mid-summer at Ems, in Germany.

H. DeC. Richards has returned to San Francisco from New York.

B. Dunstan has been appointed Government Geologist in Queensland.

John Hays Hammond is a candidate for Vice-president of the United States.

Edgar A. Collins will sail from Liverpool, on June 17, returning to Tonopah.

B. L. Thane is superintendent of the Eagle River mines, near Amalga, in Alaska.

W. A. Scott, representing the Mining and Scientific Press, is at Goldfield, Nevada.

H. E. West has returned to England from Siberia. He is now at Torquay, in Devonshire.

H. Kenyon Burch is mechanical engineer to the Moctezuma Copper Co., at Nacozari, Mexico.

William G. Devereux, of W. B. Devereux & Sons, New York, is here, on his return from Nevada.

David Goodale is manager for the Compañia Minera Rio Tinto Mexicano, at Tanazas, in Chihuahua.

Scott Turner will accompany T. A. Rickard on his journey to the principal mining regions of Alaska.

Alexander Sharp, manager of the First Thought mine, in Washington, has gone on a visit to Scotland.

John A. Reid postponed his departure from Triunfo, Lower California, but will sail by the *Curaçao* on June 6.

Frank Robbins has moved his office from the Citizens National Bank Bdg. to the Union Trust Bdg., at Los Angeles.

P. R. Whitman has left Concheño to become cyanide superintendent with the Indé Gold Mining Co., in Durango, Mexico.

Ernest A. Haggott, of Los Angeles, has been examining mines in Arizona, and is now in the Alamos district of Sonora, Mexico.

Harold B. Goodrich, manager of fuel-oil properties for the Santa Fé railroad, is examining oil-lands in California on behalf of Spurr & Cox.

H. L. Hancock, general manager of the Wallaroo & Moonta copper mines, in South Australia, has been visiting the copper region of Michigan.

General Mining News.

ALASKA.

The Rampart district will be a prominent producer again this summer, and it is estimated that the winter output now on the dumps will amount to $125,000.——The hydraulic plant, which was formerly on Big Minook creek, has been moved to Hoosier creek and will be put in operation.——The steamer *Northland* recently sailed from Ketchikan with $50,000 worth of hoisting machinery, air-drills, and other machinery for the Cymru Copper Co., at North Arm, which has been shut down several months on account of the loss of all its machinery by fire.——It is reported that the smelter of the old Alaska Copper Co., at Copper Mtn., on Prince of Wales island, has been sold, and that the new owners will remodel it and install cheaper transportation of the ore from mine to smelter.

ARIZONA.

COCHISE COUNTY.

The Willie Rose property, near Paradise, which has been idle for some time, will resume operations during June. The president is in the East selling stock and has already sold enough to assure the starting.——A sheriff's order has been issued for the sale of thirteen mining claims belonging to Cochise Con. Copper Co. near Paradise. The date of the sale is June 27.

GILA COUNTY.

The Orphan Copper Co. is building two miles of wagon road to the site of the new shaft which is to be sunk starting next month, and is moving the sinking machinery out. A 6-ft. vein of iron sulphide assaying $21 in gold and 25% sulphur has been uncovered on the Contact claim, about six miles southwest of Globe.——The May output of the Old Dominion mine at Globe was nearly 3,000,000 lb., a record surpassed only once in the history of the company, in October, 1907. Five furnaces were in commission three weeks of the time, and four furnaces the remainder of the month. A large percentage of the ore smelted was from the company's own mines.

MOHAVE COUNTY.

Water has been pumped from the Nighthawk shaft and the work of examining the property will soon be commenced. The shaft is to be sunk deeper and new backs of ore will be opened.——The suit of Nellie B. Kemper against the New Comstock Mining Co. has been compromised and a settlement effected which will result in the operation of the properties again. The company is the owner of the Katherine, the Sheeptrail group, and other mines in the part of country west of Union Pass. It also owns the Pyramid 20-stamp mill, on the Colorado river.——The Idaho-Columbus mill has just completed a run on Vanderbilt ore and made a most satisfactory clean-up. There were about 200 tons of ore milled for lessees and the concentrated product is being shipped to the smelter.

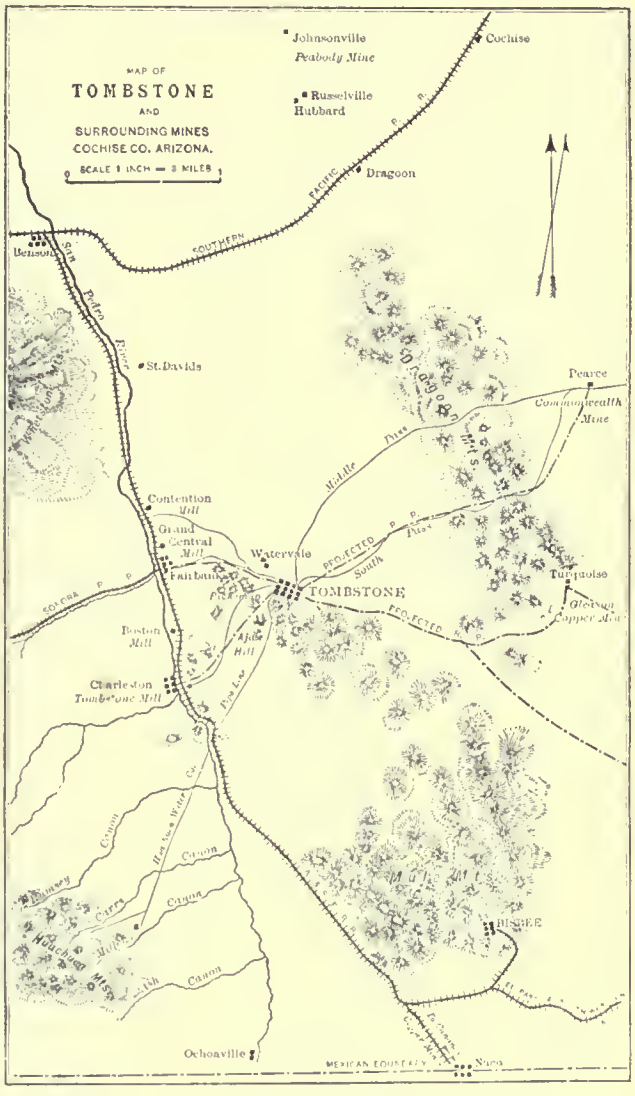
CALIFORNIA.

ELDORADO COUNTY.

The Eureka shaft, at Georgetown, will be unwatered and the shipment of ore started at an early date.——Frank Porter has bonded his mine north of Georgetown to C. G. Johnson. Development will be continued on a more extensive scale and later the working force will be increased. ——The Garden Valley Gold Mining Co. has been organized to work the Hume mine, near Georgetown, and will install machinery to work the mine. H. H. Hicks will have charge of the operations.——G. E. Lukens & Sons have incorporated the Lukens Gold Mining Co. to work their mine near Pilot Hill.

NEVADA COUNTY.

(Special Correspondence).—The 400-ft. adit at the Belle Union has cut an 18 in. vein of milling ore. A south drift is being run to develop the vein and a north drift will be started soon.——At the Union Hill extensive work is going on in the upper levels. It is reported that a new mill will be erected in the course of the next few months.——Rich gravel continues to come from the Weare property, on Banner Mtn. Local people expect to acquire the property if tests of the gravel, now under way, come up to expectations.——Several blocks of ground in the Champion mine have been leased to tributers. It is still unknown whether or not the English syndicate will exercise its option on the property.——Schlatter & Damon have resumed operations at the old Cotton Hill mine, near Washington. The 1200-ft. tunnel will be continued and developments vigorously pushed. The six-stamp mill will start as soon as enough ore has been extracted.——The Giant King mine has passed into the hands of the Western Development Co.



Southeastern Arizona.

for $35,000 in cash, stocks, and bonds. An adit is being driven to cut the main vein, which is from 50 to 100 ft. wide.——The Grey Eagle mine, at Washington, has been sold to the State for taxes. State and county taxes having not been paid for the past five years. Operations will still continue at the property.——Preliminary preparations for the starting of work on the big tunnel of the Nevada County Deep Drainage & Development Co. are under way. The road from the main thoroughfare to the tunnel site has been graded. George W. Downey will direct the work. ——The shaft at the Ethel mine has been unwatered and some good ore is exposed. Active operations will soon be resumed.——Work has commenced on the adit of the Selma mine. Development will be pushed vigorously.

Grass Valley, June 8.

PLACER COUNTY.

The Pioneer mine, near Damascus, has been leased to

H. T. Power.——The Pedlar, near Towle, has been leased to Willis Abbott and others. The dump is being treated at the Southern Cross mill.

SAN BERNARDINO COUNTY.

The Hart Florence Mining Co. is being incorporated to work the Florence group of claims, at Hart. The new company guarantees an expenditure of $15,000 for development purposes and expect to be working 10 men by June 20.——The first shipment from the Sloan lease on the Jumbo has been sent to the Cyrus Noble mill, at Searchlight.

SISKIYOU COUNTY.

The Ed Quigley mine, in Oro Fino, has been bonded to Fowler and others, who will start development at once. ——Filippe Bro., of Hawkinsville, have sold their mining property to a company of San Francisco men. The purchasers have let a contract for the sinking of a 100-ft. shaft.

TUOLUMNE COUNTY.

The motive power of the Soulsby mine, at Sonora, is to be changed from water to electricity.——It is reported that the Mack, near Big Oak Flat, will sink a new shaft. ——The Realization claim, on the east bank of the Tuolumne river, near Sonora, has been sold to H. M. Mitchell, of Healdsburg.——The Black Oak has started a small force of men stoping on the 300-ft. level, to which point the Cornish pump has lowered the water. Ten of the 40 stamps are crushing old ore which was left in the bins. The pumping still continues.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A new strike is reported this week from the Sporting Times mine, Alpine Mtn. In running the drift west a streak of heavy lead ore has been exposed that is from 4 to 6 in. wide, and assays 2 oz. gold, 20 oz. silver, and 52% lead. The drift has now cut under the old shaft workings, and a raise has been started. Shipments are to be started next week.——There is general activity throughout the Atlantic and Daily districts. Prospectors and owners are daily arriving in that locality, and the present summer promises to be the best year since the discovery of that district.——The American Sisters mine, on Columbian Mtn., was sold last week to Jas. A. Mears, of New York City, representing a syndicate of capitalists. It is reported that the consideration is $200,000, and that a cash payment of $50,000 was made. The purchaser has already started work. The Headlight shaft is to be sunk 100 ft. deeper, from which point levels will be extended both east and west. S. Peacock, a mining engineer, with headquarters in Chicago, spent three weeks in making an examination of the mine, and it is upon his report that the deal was closed. This property has been operated during the last three years by the Two American Sisters M. M. P. & E. Co., during which time regular shipments have been maintained. The holdings are equipped with a 20-drill compressor and other necessary machinery, as well as a modern concentrating plant with a capacity of 25 tons daily. The electric plant, located two miles below Georgetown, was not included in the deal. ——Work has been started upon the Drummond group of claims. The winze from the adit level has been unwatered and now driving is under way. A streak of ore is exposed that is from 8 to 14 in. wide, and assays about $45 per ton in silver and lead. Shipments are promised during the present month.——It is understood that work in the driving ahead of the Vidler tunnel will be put under way inside of 30 days. The tunnel on this side of the mountain has been driven 3800 ft., while on the western side it is 700 ft. long. It will only be necessary to drive 2800 ft. before the connection is made, at which time an outlet will be furnished for the ores of the Montezuma district, Summit county. Stock is now being offered in the Argentine Central Ry. for the extension of that line to Montezuma, so it is a foregone conclusion that the road will go through the Vidler tunnel. This practically means that the holdings of the Waldorf Con. M. Co. and the Transcontinental T. & M. Co. will be consolidated in the near future. The deal has been pending for over a year, and this practically led up to the dissensions which arose between the American and British stockholders of the Transcontinental Co., forcing that company into bankruptcy. R. C. Vidler, the promoter of the enterprise, had long been desirous of building a railroad from Denver which would go through the tunnel, and to that end the Denver & Transcontinental Ry. Co. was organized, with a capitalization of $20,000,000. with the Argentine Central utilizing that route, Mr. Vidler has decided upon another line, alleging that he will save over 100 miles over the Vidler tunnel route.

Georgetown, June 6.

GARFIELD COUNTY.

The coke ovens of the Colorado Fuel & Iron Co., at Cardiff, three miles south of Glenwood Springs, have been re-opened with a force of 200 men. The Spring Gulch coal mines, which were opened about a month ago, supply the ovens, and the coke is used at the company's plant at Bessemer.

GILPIN COUNTY.

S. T. Harris, of Russell Gulch, has taken a lease and bond on the Rockford property, south of the Topeka mine, and the machinery which has been on the Forfar mine, on Pewabic Mtn., is to be moved and installed at once. The 200-ft. shaft is to be cleaned out, re-timbered, and put in working shape.——The shipments of ore from the Two Bros. for May will reach nearly 1200 tons.——The Golden Geyser M. & M. Co. is to transfer its holdings to a syndicate of Boston men. The property consists of 30 claims, on the east side of Jenny Lind gulch, and includes a millsite. It is reported that the new company will build a 15-stamp mill at once.

LAKE COUNTY.

The Douglas mortgage on the Matchless mine has been paid, and extensive developments will be started at once under a lease given to Denver mine. Some of the old machinery will be replaced and the old workings put in shape.—— It is again reported that the Little Evelyn property in Big Evans gulch is to be re-opened, with improved machinery and facilities for handling large amounts of material.—— Work has been started on the Siwatch adit, which is to develop and drain the country around Colorado gulch and West Sugar Loaf Mtn.——Progress during May on the Dinero adit amounted to 245 ft., making a total length of 2669 ft., leaving a little over 600 ft. which must be driven before the vein will be struck.

OURAY COUNTY.

The Treasury Tunnel, near Red Mountain, is to be opened as soon as the railroad is in operation.——Again the news comes that George Crawford will clear his properties in the Red Mountain district of indebtedness and start on all of them.——The San Antonio mine is among the properties which are anxiously awaiting the opening of the railroad, presumably June 15, in order that shipments may be started.——The Barstow mine at Ouray is being cleaned out preparatory to resumption.

SUMMIT COUNTY.

Work on the Wellington mill, at Breckenridge, has been started, and it is the intention of the company to push construction vigorously. Franz Cazin has charge of the construction.——The passenger trains of the Moffat road are running regularly to McCoy siding, about two miles from McCoy post-office.——The Kimberly mill, at Kokomo, on which work was abandoned last fall on account of the depression, will be completed at once.

TELLER COUNTY.

The British-American M. & D. Co., Cripple Creek, shipped 65 cars during May from their lease on the south end of the Dante property, on Bull hill.——A rich strike is reported at the 250-ft. level of the Cobb shaft on the Moon

Anchor.——The repairs to the hoist at Vindicator No. 2 have been completed, and Whitney & McMullin, the lessees, will continue the regular shipments.——The face of the drainage tunnel is now in 2484 ft. and was advanced 268 ft. during May. Work was stopped this week, caused by an accident to the compressor.

TELLURIDE COUNTY.

The Silver Chief property, on Bear creek, has been sold to a company of Pennsylvania men. J. B. Olsen, who had an option on the mine and has been operating under leases for some time, will be general manager for the new company.

IDAHO.

BLAINE COUNTY.

The Boston Idaho, on Boyle Mtn., will practically rebuild its mill and has recently purchased a large amount of new machinery. The new mill will use water-power and will have a capacity of 100 tons per 24-hr. day. The company will also construct tramways from its Lucky Boy and Sunday properties to the mill. A contract has been made with the American Metal Co. to take all the zinc ores for a period of five years, payment to be made on a sliding scale.——It is reported the Willow Creek Mining Co., near Hailey, will build a 10-stamp water-power mill.

BOISE COUNTY.

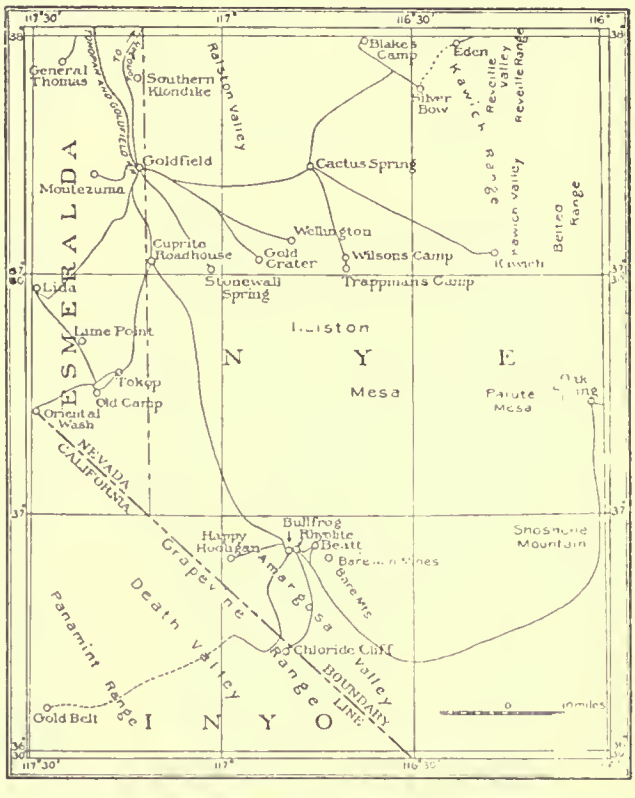
It is reported that a mill will be built at the Switzerland claim, belonging to Leo & Antone Unternahrer, in the Hay Fork district, 14 miles northeast of Idaho City. An 80-ft. head is available for water-power. A number of other mines in the same district, though not thoroughly developed, show good prospects.——A. C. Springer, of Boise, has secured an option on the Easter Sunday property, in Thomas gulch. A 300-ft. adit will be driven to strike the vein at a depth of 150 feet.

OWYHEE COUNTY.

A company has been organized to continne work on the Sunnyside group of claims, near the head of Succor creek, 12 miles from Silver City. This property made quite a production last year, at which time a small mill was constructed.——It is probable that the Banner mill, at Silver City, will be running at the time of the annual meeting of the company, June 24.

SHOSHONE COUNTY.

(Special Correspondence).—Mining activity in the Coeur d'Alene is increasing from day to day and now all the big producers, closed down during the recent depression in the metal markets, have again resumed with full forces. The Morning mine, at Mullan, resumed this week, and a force of not less than 400 men will start work as soon as they can be gathered.——Men are arriving in the district nearly every day for work in the Hecla mine at Burke. Yesterday a force of 70 men started at this property, making a total of about 170 now employed. This is the normal force, but it is the intention of the company to increase the output, and the pay-roll will be increased to about 300 men in the near future. Shipments are to begin again this week. ——The Bunker Hill & Sullivan mine, at Wardner, paid its 129th dividend today. This amounts to $75,000, and the total distributed by the company for this year is $405,000, while the grand total under the present management is $10,221,000. A full force is engaged at the mine, and it is generally expected that the monthly dividends will be materially increased in the near future.——It is expected that the Minemakers' Association will issue their blue-book of the district some time during the present month. Owing to some complications the time for receiving reports on properties has been extended until June 15. This book will contain a description of all the prospects and mines of the district, supplied by the secretary of each, and attested under oath.——The new mill at the Charles Dickens property is nearly complete and will be in operation in the next few days. The cost of the mill was in the neighborhood of $25,000, and the capacity is about 75 tons per day.——The Coeur d'Alene Investment Co., of Mullan, has made its final payment on the property of the Keystone Mining Co., in Spring gulch. The property has been under bond for $20,000 since November, 1906. Already the mine has shipped more than $200,000 worth of ore from the surface.——A body of ore valued at not less than $100,000 has been opened up in the property of the Nipsic Mining Co., at Burke, adjoining the famous Hercules mine. A raise is being driven from the third to the second level, and this has been in ore all the way, a distance of about 105 ft. It has still to be driven about 30 ft.——The Coeur d'Alene Vulcan property is now engaged in constructing a 1500-ft. flume and a 600-ft. penstock, by the use of which power will be derived for driving a Pelton water-wheel. A 3000-ft. cross-cut has been started, which will intersect three veins and tap the most southerly at a depth of about 2000 ft.——A 300-ft. shaft is to be sunk on the property of the Bullion Mining Co., near Saltese, and work will be commenced in the course of another week. This will be sunk from the No. 2 level and will give a depth of about



Part of Nevada.

500 ft. on the ore.——At a recent meeting of the directors and stockholders of the Imperial Mining Co. it was decided to increase the capital of the company from $1,000,000 to $1,500,000. The whole of the increase will be placed in the treasury, to be sold for development purposes.——An assessment of three cents a share has been declared on the capital stock of the Copper King Mining Co. The company is capitalized at $1,500,000, and the money will be used to drive a 3600-ft. adit on the property to give a depth of about 1200 ft. on the vein. The cost of this tunnel is estimated at $45,000. The assessment is payable in three instalments at intervals of six months each.——An unconfirmed report has reached Wallace to the effect that a large body of ore carrying appreciable quantities of copper and gold has been encountered in the big tunnel being run by the Chicago, Milwaukee & St. Paul railroad at Saltese. The tunnel is 1000 ft. long, and is situated on Dominion creek.——The recent strike on the property of the Cedar Creek Mining Co. has now been definitely ascertained to consist of five feet of good concentrating ore. This strike was made at a distance of about 500 ft. from the portal of the tunnel and at a depth of about 360 feet.

Wallace, June 9.

NEVADA.

ESMERALDA COUNTY.

The Quartzite Annex Mining Co. is moving the 30-hp. hoist from the Scully lease on the Sandstorm, to its property which adjoins the Jumbo Extension and the Triangle. The machinery is being erected on the Lulu No. 1 claim.——The old Junatlanta lease, which was recently forfeited, has been secured by a Milwaukee syndicate. Work will begin June 15, and the 270-ft. shaft will be deepened to 500 ft. ——During the four days allotted it by the arbitrators, the Mohawk-Combination hoisted 930 tons of ore, of an average value of $75 per ton.——The management of the St. Ives Leasing Co. has decided to sink the main shaft on the St. Ives claim 50 ft. deeper. The production of the Goldfield mines for the week ending June 5 was 2407¼ tons, valued at $188,759. The Tonopah mines produced 5758 tons, of an estimated value of a little over $100,000.

LINCOLN COUNTY.

The Searchlight-Midas Mining Co. has let a contract for sinking its 230-ft. shaft 70 ft. deeper. The property is a short distance east of Searchlight.——The California-Pioche has struck a body of rich ore in its shaft, at a depth of 180 ft. The showing is so favorable that a 40-hp. hoist has been ordered.——W. S. Anderson has ordered a gasoline engine and compressor for his mining property above Pioche.——The Ely Valley Co., operating east of Pioche, is making numerous improvements on its property, including a gasoline engine, a compressor, and several buildings.

NYE COUNTY.

It is possible that Berry & Roche may buy the plant of the Nevada Milling & Ore Purchasing Co., at Manhattan. ——The *Bullfrog Miner* gives the production of the Bullfrog mines for May as follows: Montgomery Shoshone, $86,000; Keane Wonder, $25,000; Skidoo mines, $7000; Tramp Con., $3300; Philip & Moesser Gibraltar lease, $2000; National Bank lease, $900; Original Bullfrog lease, $790; total, $124,990.——Actual construction has started on the 10-stamp custom mill of the Beatty M., M. & R. Co., at Beatty.——The only hydraulic mine on the Great American Desert is being operated by the Round Mountain Hydraulic Mining Co. They are operating three monitors, and it is claimed they are cleaning up $1000 per day.——Arrangements have been completed with the Belmont Co. by which all future operations in the North Star and Rescue will be carried on through the Belmont shaft, and work through the shafts of the former companies will be abandoned.

WHITE PINE COUNTY.

(Special Correspondence).—Renewed activity is reported from Hamilton and the adjacent district. This camp, which is 20 miles due west of Ely, is the oldest in Nevada, and produced, between the years 1868 and '73, $40,000,000 worth of silver bullion, and during that time boasted a population of 20,000 people. Since then, however, the camp has been forgotten in the mining world. A number of the properties in the district have been worked spasmodically, and have produced enough silver to furnish a livelihood for the 300 people remaining. The McEllin, 3½ miles northwest of Hamilton, is working six men and extracting $30,000 to $35,000 each season. The Nevada Lead Co., operating on a neighboring property, is a newcomer, but already has a large quantity of ore on its dump and will proceed with active mining this season. The Alta Zoanni group, near the summit of White Pine Mtn., has some high-grade silver-lead ore in sight, and also a carload on the dump which is to be shipped soon. Other promising properties are the Rocco-Homestake, the Roosevelt, and the Julia No. 2. A total shipment of 2500 tons from the Hamilton district is predicted for the coming season.

Hamilton, June 5.

It is possible that the Ely Central will sink a number of shafts on its property between the Ruth and Copper Flat groups of the Nevada Con.——The French-American Mining Co. has started work on its Duzette group, near Lane City. Samples of the ore from this property assay 27% copper, $14 gold, and 11 oz. silver.——The Veteran has been hoisting about 400 tons per day, and this output will be greatly increased within a week or ten days, when the electric hoist is put into commission.

MICHIGAN.

James L. Nankewis, Commissioner of Mineral Statistics for Michigan, has issued a resumé of the important facts in his forthcoming annual report for 1907. He reports, on a whole, a favorable outcome of the year's operations. The number of men employed in the mines was larger than that of any previous year, and several companies made record productions of copper. The average total of the men employed in three counties of Houghton, Keweenaw, and Ontonagan was 21,014. The copper production was 220,217,892 lb., being a decrease of 2% compared with 1906 and an increase of 1% over 1905. Dividends paid, including the Copper Range Co., the St. Mary's Mineral Land Co., and the Union Land Co., amounted to $15,114,700. The Copper Range, the Quincy, the Tamarack, the Mohawk, and several others, each produced more copper in 1907 than in the previous year.——The Michigan mine, at Houghton, has recently received five cars of Woodbury jigs for the mill.——The Champion has installed at the C shaft a Nordberg hoist which will enable them to sink to the 8000-ft. level. It will be in commission about July 1.

MONTANA.

Excessive fall of snow and rain during May caused severe floods throughout the State, resulting in considerable damage to property and loss of life. Several mining properties were compelled to close and suffered no small loss. The railroad between Great Falls and Helena suffered such a serious washout that it will require two months to repair the damage. During that time the smelter of the Boston & Montana will have to shut down, and consequently the Boston & Montana mines, at Butte, will also be closed, and as a result five thousand men will be thrown out of employment. A cloud-burst on Wednesday night caused a washout on the Butte, Anaconda & Pacific railway, and compelled the Amalgamated, the North Butte, and the Coalition mines to close. The break will be repaired in a day or two.

UTAH.

JUAB COUNTY.

The Iron Blossom has cut ore on the 600-ft. level.——The Tintic Silver Co. has been incorporated to exploit the Lake View and the Blue Point claims in the North Tintic district.——The Raymond-Illinois is ready to resume development, the water which accumulated during the repairs having been removed.——The shipments from the mines of Tintic for the week ending June 5 were as follows: Centennial-Eureka, 38 carloads; May Day, 4; Eureka Hill, 11; Yankee Con., 1; Bullion Beck, 2 carloads.——It is probable that the Eagle & Blue Bell mine, at Park City, will be opened within a week or ten days.——Work has been resumed in the winze of the Sioux Con. of Tintic.——Eleven cars of ore from the Silver Shield mine, at Bingham, arrived at the new Tintic smelter this week. The plant will not be ready to run, however, until July 1.

SALT LAKE COUNTY.

The Commercial mine, at Bingham Canyon, has resumed with two shifts.——The Utah Copper has installed two Chilean mills at its plant.——It is reported that the New England Gold & Copper Mining Co. will resume production after the meeting of the directors at Denver on July 15.

SUMMIT COUNTY.

It is reported that the Daly and the Naildriver properties, at Park City, will resume soon.——The official survey of the Park-Virginia property, formerly the Clark-Virginia, was completed last week and it is expected that development will be undertaken at once.

UTAH COUNTY.

Jesse Knight has purchased the controlling interest of

the Major Evans Con. M. & M. Co., whose property is in the American Fork canyon. This is the second property in the district to be taken over by the Knight interests, the Mineral Flat having been acquired last summer. The new acquisition is near the Mineral Flat.

WASHINGTON.

OKANOGAN COUNTY.

(Special Correspondence).—The Q. S. Mining Co. has all the machinery for its power plant on Sinlahekin creek, on the ground, but has delayed its installation pending the adjustment of some internal affairs of the company which will eventually lead to re-organization. The Q. S. vein has been intersected at a vertical depth of 800 ft. It assays as high as 20% copper, but the average content is 3.6%. Work in the lower adit has been suspended pending the re-organization referred to. When the Okanogan Electric Railway is completed the company expects to begin regular shipments.——The Arlington mine, in the old Ruby camp, is driving a 1000-ft. adit to strike the vein at a depth of 400 ft. There is now a shaft on the vein, from which rich argentine and native silver have been taken.——A water-right has been located on Salmon creek for the Okanogan Electric Railway.

Oroville, June 8.

STEVENS COUNTY.

(Special Correspondence).—The Gem mine, near the Trojan, in Pierre Lake district, has started active operation. ——The Napoleon mine will soon work a full force of two shifts and expect to ship from 150 to 200 tons per day to British Columbia smelter, at Greenwood, B. C.——The Deer Park Mining Co. has three men employed and it is believed they have struck rich ore, although the management is giving out no information.

Metaline, June 9.

CANADA.

BRITISH COLUMBIA.

The St. Elmo property, 11½ miles from Rossland, has been leased to John Selda and associates, for 18 months. This mine was last worked about six years ago, at which time there was a good deal of ore blocked out, which will now be shipped.——The gross output of the Le Roi mine for the month of April was nearly $90,000, which is a little more than the average.——The Pot Fraction has been leased to Hooper, Dailey & Nottinger for three years.—— The Golden Rule management has let a contract to sink its shaft 50 ft. deeper.——The lessees of the Evening Star, which has been idle for several weeks, have resumed.

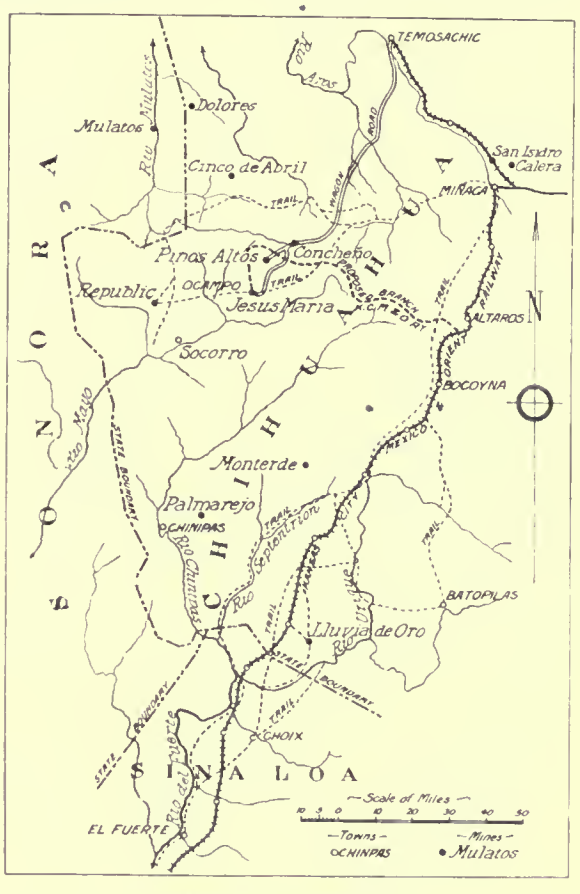
Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending May 30, and for the year to date:

Mine.	Week.	Year.
Centre Star	2,956	73,111
Le Roi	1,890	35,739
Josie	315	11,534
California-Giant	....	95
Blue Bird	....	110
Red Eagle	....	20
Evening Star	....	128
Totals	5,161	121,037

At the smelter of the Consolidated Co., at Trail, there was received during the past week 5291 tons of ore. Besides that shipped from Rossland, other mines sent in ore as follows: Ymir, 21 tons; Hewitt, 22; Richmond-Eureka, 48; Snowstorm, 776; First Thought, 138; St. Eugene, 212; Giant, 18; Silver Cup, 39; True Fissure, 53 tons.

MEXICO.

The Benito Juarez Mines Co. is receiving the machinery for its 150-ton mill and cyanide plant at Peñon Blanco, S. L. P. The plant will consist of a battery of twenty 1050-lb. stamps, dropping in deep mortars of the El Oro type; a No. 4 Gates crusher, a 16-ft. wet grinding tube mill, and a Dorr classifier. There will be 23 steel cyanide tanks for sand and slime treatment, and a complete precipitating and refining outfit. Both the mill and the several mines of the company will be operated by electric power. The company has suspended ore shipments and is storing its ore pending the completion of the mill.——A new company has been organized to take over the Guadalupe mine in the Ejutla district of Oaxaca. The shaft is 285 ft. deep and will be sunk to the 400-ft. level and a drift run at the 300.——The Los Arcos M. & S. Co. has temporarily closed its smelter and is making preparations for the erection of a 100-ton concentrating and cyanide plant at its mines in the Sultepec district.——Grading has been commenced for the new 5-stamp mill of the Chicago-Mexican Mining Co., near Cusihuiriachic, Chih.——A 30-ton reduction plant, consisting of stamps, concentrating tables, and a cyanide annex, will be erected on the El Tajo mine of the El Tajo Mining Co., at San Sebastian, Jalisco. It is estimated that the milling ore now available is sufficient to keep the mill busy for several years.——In the new stamp-mill of the Mexican Mining Co. at La Luz, Gto., the mill will be operated without cams, the stamps being worked by a line shaft and eccentrics instead of with a cam arm and shaft. The stamps will fall 200 times per minute by the new process. The mill capacity will be 50 tons.——The Santa Lucia mine, at Balsas, Gro., will be operated on an extensive scale this summer. Three miles of railroad will be built to connect with the Mexican Central and a 150-ton smelter installed. ——The Sierra Madre y Pacifico railroad, now operating from Ciudad Juarez to Casas Grandes, Chih., will be extended probably this year to Madera, Chih., the seat of W. C. Greene's lumber operations.——The San Carlos copper mines, San Jose, Tamps., are expected to resume operations some time this month. The property is owned by the Nichols Chemical Co., of New York, and is equipped with smelter and reached by a branch line of railroad. The deposit is extensive but low-grade, yielding mostly copper. ——The Grenadeña Mining Co., Santa Barbara, Chih., will build an aereal tramway 5 km. long from its mines to its mill. It will have a capacity of 10 tons per hour. It is reported that the mill will be started up again within the next month. Sewell Truax is manager.



Map of Part of Mexico.

Special Correspondence.

LONDON.

Wild-Cat Booming of Russian Mines.—Tanganyika Concessions.—Mt. Lyell Report.

Between two and three years ago a great deal was heard in London about the wonderful properties in Russia acquired by the Siberian Proprietary Mines, Ltd., otherwise Mr. Hyman Orkin. Gold deposits of great value had been leased in the Kotchkar district of Orenburg, and copper and coal properties in the Pavlodar district of Semipalatinsk. The capital of the company was originally £100,000, of which £65,000 was issued fully paid as purchase price, and the remainder was subscribed at an average premium of 100%. Just a year ago 16,000 new shares were issued at £12 10s. each, that is, at a premium of 1150%, a fact which indicates pretty fairly the nature of the boom. Two subsidiary companies have been formed to acquire gold mines in Orenburg, one the Orsk Goldfields, Ltd., and the other the Troitzk Goldfields, Ltd. The issued share capital of both of these is £500,000, of which £251,000 in each case is retained by the parent company. When the two subsidiary companies were promoted, the whole of the share capital was allotted to the parent company, credited with about two-thirds paid up on each share. The idea was that the remainder of the liability on each share would be paid up by the parent company and would form the working capital. It will be seen, however, by examining the accounts, that enough of the shares were sold in the open market at high premiums to pay off the liability on the remaining shares, to provide working capital, and to give a certain amount of profit in other directions. In the midst of this boom there were not wanting skeptics, and those who knew the properties personally uttered warnings. At least one of the independent mining papers had something to say about it. Later on, the promoters were forced to set their house in order, and Messrs. Hooper & Speak were appointed consulting engineers. This firm soon found out that the prospects were quite commonplace affairs, instead of bonanzas. The properties belonging to the Orsk company have been turned down, but as the lease does not expire for nine months a little exploratory work is still being done. The Troitzk company's property is doing better, for the deposit, though of low grade, is fairly extensive, and it is intended to erect new plant to treat 5000 tons per month. The Pavlodar coal and copper properties have not yielded much so far, and the consulting engineers recommend that exploration work with the diamond drill shall be done on the copper properties. Owing to the method of financing the subsidiaries, the Siberian Proprietary still has the bulk of its capital intact, and has over £180,000 cash in the bank. There have been a good many re-arrangements in the constitution of the directorate. Edward Hooper has joined the board and Mr. Orkin has relinquished his special powers and emoluments. Under the new régime it is more than probable that the company will after all attain an honorable position.

The copper deposits in the central parts of Africa are now exciting increased interest in London, and Mr. Farrell's article in your issue of April 18 on the Tanganyika Concession's properties was specially welcome at the present juncture. There are several other copper deposits of great promise in Africa, but very little has been published relating to them. One of the most important of these is the Bwana M'Kubwa, which is situated about 150 miles to the southeast of the Kansanshi. This property belongs to the Rhodesia Copper Co., which is one of the subsidiaries of the Northern Copper (B. S. A.) Co. Owing to the difficulties of communication and transport, progress at the mine has not been rapid, and much care has been taken not to rush things. The vein has now been proved by three shafts and two levels over a distance of 1300 ft. to a depth of 250 ft. The average width of the deposit is 4 ft., and it is estimated that there is about 80,000 tons of ore in this block averaging 15% copper, in addition to some 20,000 tons of ore running from 4 to 10%. The ore thus far found is the carbonate of copper in a silicious gangue. On each side of the vein the sandstone is impregnated with carbonate of copper for something like 40 ft., and the copper contents are as high as 4 to 5%. There is something like 1,200,000 tons of this class of ore so far developed. At two points the workings have been carried a hundred feet lower, and as far as the development has gone, the ore continues to be of the same character. The question of the most suitable method of treating the ore is engaging the anxious attention of metallurgists, who are studying the sources of supply of fuels and fluxes. The Northern Territories Co. also has a large interest in the Kafue Copper Development Co., which operates the Sable Antelope mine in the same district. This mine contains a variety of sulphides, and it has been sufficiently developed to the 300-ft. level to warrant the erection of a 25-ton smelter. There are also two other properties that are coming forward well, one, the Messina in the Northern Transvaal, and the other the Edmundian, in Portuguese territory, between Beira and

Salisbury. But of these two I will write on another occasion.

In December last I referred to the confusing method adopted by the Mount Lyell Co. in publishing the results for the half-year ended September 30, 1907. Owing to the slump in copper during that period, the prices at which the metal was sold varied greatly, and in addition a large part of the production was not sold at all. The report issued by the company did not make the situation clear, and there was in consequence much uncertainty as to the position of the company. The report for the half-year ended March 31 last contains no vagueness of this sort, and states the results of the work more explicitly. During the six months the production at the smelter was 4301 tons of blister copper, which is estimated to contain 4201 tons of fine copper, 10,489 oz. gold, and 344,608 oz. silver. At the beginning of the period, October 1, 1907, the unsold copper on hand was 2389 tons, which has since been sold at an average price of £61. Of the last half-year's production, 3311 tons were sold at an average price of £61 8s., leaving 908 tons unsold at the end of the half-year. The net profit for the half-year was £128,980, of which £105,000 has been distributed as dividend, which is at the rate of 1s. 9d. per £1 share, or 17½% per annum.

The amount of ore treated during the half-year was 202,014 tons, averaging 2.46% copper, 1.77 oz. silver, and just under 1 dwt. gold. Of this, 139,370 tons came from the Mount Lyell and 62,644 from the North Mount Lyell. In addition, 204 tons of purchased ore and 7525 tons of metal-bearing flux were treated. The ore-reserves have been con-

siderably increased during the year, and the orebodies at the 1000-ft. level at the North Mount Lyell are opening up in a most satisfactory way. On March 31 the reserves are figured as follows: at the Mount Lyell mine, available by means of open-cut, 909,471 tons, estimated to contain 0.6% copper, 1.93 oz. silver, and 0.86 dwt. gold per ton; available by underground mining, 2,613,945 tons, estimated to contain 0.52% copper, 1.97 oz. silver, and 0.5 dwt. gold; at the North Mount Lyell, 606,658 tons, of an estimated average value of 5¾% copper, 1.33 oz. silver, and 0.1 dwt. gold. The reserves at North Mount Lyell on September 30 last were 438,020 tons, so that, allowing for 63,250 tons extracted during the period, the increase has been 231,888 tons.

TORONTO, CANADA.

La Rose Consolidated.—North American Smelting & Reduction Co.—Ore Shipments.—Ore Discoveries.—Government Experiments with Peat.—Yukon Consolidated Gold.—Lead Bounties.

What is likely to be a notable event in the history of Cobalt is the accomplishment of the merger of the La Rose mine with the University and several other properties, that had been for some time in contemplation. The new company is known as the La Rose Consolidated, and is capitalized at $6,500,000, the shares being placed at $5 each. The holdings, comprising in all 317 acres, embrace, in addition to the well known La Rose and University properties, the La Rose extension of 40 acres directly to the north, upon which the big veins of the La Rose have been traced; the Violet, adjacent to the La Rose and O'Brien; the Princess, situated near the McKinley and Silver Queen; the Fisher-Eplitt, and the Silver Hill properties. Of the capitalization $1,000,000 is reserved for the purchase of new properties. The board of directors comprises the La Rose owners, John and Duncan Martin, Henry and Noah Timmins, and David Dunlop, with the addition of David Faskin, of Toronto, and E. P. Earle, Richard T. Greene, and Frank Holmes, of New York. The smelter of the North American Smelting & Reduction Co., at Thorold, Ontario, controlled by the owners of the Coniagas mine, which has been for some time under construction, has finally been completed and put in operation with a force of about forty men. Tests of the furnaces were made on June 2, and proved completely satisfactory. Cobalt ore from the Coniagas mine has been received to the extent of several carloads and is now undergoing treatment. For the present, operations will be limited to the Conlagas output, but an extension of the plant is contemplated which will enable the smelter to receive other ore. Heavy shipments of Cobalt ore continue, the total for the week ending May 30 being 459 tons from the following mines: Coniagas, 31 tons; Drummond, 28; La Rose, 30; McKinley, 33; Nipissing, 92; O'Brien, 127; Silver Queen, 55; and Tretheway, 72 tons. An important strike was made on the Nipissing property on May 29 by a diamond drill in a vein situated between the Big Bonanza or 49 vein and the Kendall vein at the south end of Cobalt lake. The ore showed a width of 4 in., and carried 3500 oz. silver per ton. The vein is supposed to form a connecting link between vein 49 and the Kendall, which are over ¼ mile apart. Great progress is being made in development work. The eastern extension of vein 49 is being worked by open-cut. An adit is being driven in from the shore of Cobalt lake, and is now in 1000 ft., for the delivery of ore from veins 26, and eastern extension of 49, Kendall vein, and Promise vein to a concentrator to be built at the mouth. It will also serve the purpose of giving needed ventilation to the workings. The Promise vein is the continuation on the Nipissing of the Niccolite vein now under development on Cobalt Lake and a shaft is being sunk to prospect it close to the Cobalt Lake workings. A station is being cut at the 140-ft. level on the Kendall vein, from which driving will be done. A large addition to the force has been made for surface prospecting. A shaft is down 75 ft. on the property lying to the north of Cobalt town on a vein which has been identified as being the rich vein on the Tretheway. A new 250-kw. generator of 2000 volts, and a high-speed engine, have been installed to furnish power for the entire mine equipment. A car of 32½ tons of ore recently shipped from the Silver Leaf has netted $160,000, being one of the richest shipments ever made from the camp. The main shaft on this property is now down 150 ft., and the vein at the bottom of the shaft is 4 in. wide, and carries about 5000 oz. silver per ton. A rich vein was lately struck in cross-cutting at the first level on the Nancy Helen, when a 5-in. vein containing native silver in large quantities was encountered, which is believed to be an extension of Buffalo No. 4.

The Canadian Department of Mines will undertake a series of experiments with a view to utilizing the extensive peat deposits of Canada. A Swedish expert conversant with European methods has been secured, and an experimental plant will be established, probably in Ottawa, where investigations will be carried on in the methods of obtaining producer gas from peat, as well as other means of utilizing peat industrially. An examination as to the extent and quality of Canadian peat beds will also be made.

The Yukon Consolidated Gold Fields Co. has secured the services of six men from the Toronto School of Science to take charge of a portion of its hydraulic mining system about 15 miles from Dawson. The party, which has left Toronto for the Yukon includes K. A. Mackenzie, R. E. W. Hagarty, C. R. Murdock, J. A. Walker, J. E. Gray, and C. S. Cameron. These are the first Canadians engaged for engineering work by the Yukon company, which has hitherto employed graduates of American colleges for this class of work. The Canadian Minister of Finance has introduced into Parliament at Ottawa a resolution extending the bounties on lead mined in Canada for another five years, which would otherwise expire at the end of June. The conditions are made more favorable to the lead miners. The former legislation provided that the amount so paid should not exceed $500,000 in any one year. By the present resolutions the total for five years is fixed at $2,500,000, without limitation as to each separate year's payments. The amount of the bounty is the same as before, $15 per ton, but while formerly the rate was reduced when the price reached £12 10s. in England, and the bounty ceased altogether when the English price rose to £16, the new resolutions fix the point at which a reduction is to be made at a standard selling price of £14 10s., the vanishing point remaining as before.

MEXICO.

New Mining Law.—Restrictions on Foreign Companies.—Chamber of Mines.

It would seem from recent circumstances, notably as reflected in several articles of the proposed new mining law, that an anti-foreign feeling was coming to the surface even among the better class of the Mexican people. When, two years ago, an anti-foreign scare was discussed in the papers, and it was rumored that on September 16, 1906, all foreigners would be killed or driven out of the country, it was stated that such feeling as existed in the Republic was limited to the laboring classes, particularly along the railroads, and near the International border. But now objection to the foreigner seems to be manifest in the more enlightened circles; in the Congress of the Republic; and in one of the Government departments. But a few weeks ago Lic. Rosendo Piñeda, a lawyer of Mexico City and a member of Congress, proposed an amendment to the Constitution, placing restrictions upon foreigners in the practice of the professions, particularly that of the law, in the Republic of Mexico, and during the past week an absolutely prohibitory measure, aimed at foreigners, has been learned to exist in the proposed new mining law, which has been drafted at the instance of the minister of fomento, Lic. Oligario Molina. The sections referred to deny to foreigners the right to denounce or obtain mining properties in Mexico, and prohibit foreign companies from acquiring title to mining properties in the Republic. The articles embodying these prohibitions are in full as follows:

Art. 141.—No title deed for mining property can be issued

to foreigners denouncing properties within the bounds of border States, if they do not previously obtain a special permission from the executive of the Union. This requirement will also be exacted when the denouncement is made conjointly by foreigners and Mexicans. If the permission is refused, the ground shall be declared free, and the same effects result as those consequent on voluntary abandonment of a denouncement, as set forth in Article 36.

Art. 142.—The permission mentioned in the foregoing article will also be necessary in order that foreigners may through any other process come into possession of mining properties or liens thereon in any of the border States or Territories.

Art. 144.—Foreign corporate bodies are incapable of denouncing and acquiring henceforth, by any process, either mining properties or liens thereon within the territory of the Mexican Republic.

By the law of 1856 foreigners were debarred from acquiring land of any kind in a zone 20 leagues wide along the northern border without permission from the Federal Government. The new law would affect the entire area of the States of Sonora, Chihuahua, Coahuila, Nuevo Leon, Tamaulipas, and the Territory of Baja California. Some have held that the Government feared the growing strength of the foreign population in the North, but Article 144 of the law indicates that there is a deeper purpose. The adoption of this article would mean that every foreign company, to hold mining properties in this country, would have to incorporate under the laws of Mexico, thus requiring their head offices to be in Mexico, and their principal officers to be residents of the Republic. This would be a practically prohibitory measure. It would seem to be suicidal for Mexico to adopt this. Unless concessions are made to capital it will go elsewhere, and Mexico will be allowed to drop behind. The draft of the new law was submitted to the Chamber of Mines, which has just been in session in Mexico City, for study and comment, and by unanimous vote of the Mexican members it was decided to ask the Government to wholly suppress Article 144. During the discussion Lic. José L. Riqueña, one of the wealthiest residents of Mexico, president of the Dos Estrellas Mining Co. of El Oro, made a lengthy speech before the Chamber in opposition to the Article, and said in part as follows: "Article 144 prohibits foreign companies from acquiring by any means title to mines or real rights in them. If this prohibition should be adopted, the national mining industry will receive the most severe blow that could be given to its growth and prosperity. Mexico is a country of great natural resources but poor in capital. . . . If we need foreign capital, we will have to leave the management of the business and the administration of the companies in the countries of their origin. . . . There is then no reason for shutting the door in their faces, nor for putting obstacles in the way of their acquiring mining properties. They do not injure us. They aid us." It is to be hoped that such counsels as these may prevail, and that the hot-heads may not rush through a law which would weaken confidence in the Republic and check the initiation of new enterprises.

Mark R. Lamb announces having just closed a contract for a Moore filter of 250 tons capacity with the S. Rafael Co. of Pachuca. This contract probably marks the end of doubts as to the rights of the Moore Filter Co. in Mexico, as the directorate of the S. Rafael Co. is composed principally of attorneys of prominence. The manager, Edmundo Girault, is the consulting metallurgist, and J. B. Empson is thoroughly posted on the filter situation since the building of the first Moore filter in Utah.

The San Carlos Mining Co., of Sonora, is receiving estimates on a 50-ton plant, in which the Behrend system of dry concentration will be used. The El Triunfo Consolidated Mining Co. will also install a concentrating mill of 50 tons capacity at its mines near Arizpe Sonora, employing the Behrend dry system of concentration. It is planned to increase the capacity to 200 tons per day in a short time.

The Cananea Copper Co. has arranged with the Department of Fomento for free importation of fuel oil for its individual use, which has received congressional sanction.

JOPLIN, MISSOURI.

Flood-Damage at Webb City.—Center Creek Development.—New Concentrating Plants.—Miami, Oklahoma.

The heavy rains of the past few weeks have caused much damage to mines in the Missouri-Kansas district, especially in Granby, Spring City, Spurgeon, and along Spring river and Center creek. Some of the largest mines and best producers in the field are threatened along Center creek, in the sheet-ground camp north of Webb City. The danger is increased because of the closing down of the Vantage pumping plant, which for four years has kept the mines drained along the valley between Webb City and Oronogo. Some months ago the Vantage plant threatened to shut down on account of the heavy expense entailed, but the neighboring mines lent assistance by paying a certain portion of the expense, and the pumps were kept going until last week. The mines in the vicinity have been installing larger pumps and hope to control the water without the aid of the Vantage plant, which was the largest in the Missouri-Kansas district. There has been a great decrease in pumping in this region, about one-fourth of the mines having closed since last year, and this, together with the wet spring, has caused a heavy loss to the district. The output has been curtailed to an average slightly exceeding 4000 tons per week. This curtailment has had no appreciable effect upon the zinc-ore market. Instead of increasing the demand, the market is receding, and ore prices range from $32 to $35 per ton for 60% zinc. However, those mines producing galena in conjunction with zinc-blende are weathering the storm, as the price of galena has increased steadily during the past two months at the rate of $1 per week, until last week's sales were made upon a basis of $60 per ton for 80% grade.

The most important development work contemplated in Webb City is that being undertaken by the Center Creek Mining Co. in re-opening the ground between Webb City and Carterville. This territory has produced in excess of $13,000,000 worth of lead and zinc ore, which has come principally from the upper runs above the 150-ft. level. In obtaining this the ground was badly handled, little provision being made for pillars, and timbering was done merely well enough to hold out until the workers could get out of the way. As a result much of the ground caved, making it dangerous to attempt to win some of the richest orebodies. The ground has therefore remained idle or has been gophered by small prospectors for a number of years. The company has recently had a completed survey made of the tract, and compiled upon the plat all the workings of which there was any record, together with new surveys of more recent mines. The plat shows that the ground still has a large quantity of ore reserves above the 150-ft. level. Below this the tract is underlaid with sheet ore of lower grade. The upper ground is now being opened by the Corrie Cole Mining Co. upon a lease of several acres involving the old Beasley mine and the Good Shepherd ground. Two 250-ton concentrating plants are now being erected and upon each lease two shafts are being re-opened and cribbed. The company will first work out the upper runs and will later take up the work of exploiting the lower-grade sheet ore below. The Center Creek Co. by its recent activity adds 40 acres of the richest producing ground to the Webb City territory.

The first active production from the new Oklahoma camp at Miami began last week. The output from the Old Chief, New State, and the Emma Gordon was shipped, and raised the camp to the fifth place in the list of producers. The ore consists of both galena and zinc-blende, but the galena is unimportant. The zinc-blende, while of good quality, is associated with bitumen, which lowers the grade of the concentrate by causing gangue to stick to the blende particles. The result is that when ore is $35 elsewhere in the district, this ore brings from $25 to $28 per ton. However, there is compensation to the operator in the fact that the product as mined contains generally a large per cent of metal. The problem of separation is one which will yield a large reward for its successful solution.

DOUGLAS, ARIZONA.

Copper Queen Smelter.—Calumet & Arizona Plant.—Copper Giant at Mammoth.—Nacozari Concentrator.

The Copper Queen is at present operating only six of its ten furnaces, the total charge smelted per day being a little over 2000 tons. About 1500 tons of the ore in the charge comes from the company's mines in Bisbee; 125 to 150 tons of high-grade concentrates from the Phelps-Dodge properties at Nacozari; some rich silver ore from the El Tigre mines in Mexico, together with a small amount of custom ores from Arizona. The custom business, which a year ago accounted for a large percentage of the copper output, now amounts to very little. In the near future, when the new concentrator at Nacozari is in full operation, more than double the present amount of concentrates will be received from there. In the past considerable highly silicious ore was shipped from Globe for converter-lining, but the supply has greatly decreased and shipments to the 'Queen' from that district have ceased. The Clifton-Morenci district is shipping some converter-lining and a small amount of smelting ore. The only work of importance at the smelting plant is the renewing of a hood of one of the furnaces, and the re-construction of the down-take for the same furnace. The new copper casting-machine is working satisfactorily. The plant as a whole is in excellent shape.

The five furnaces of the Calumet & Arizona Co. are running to their full capacity, having smelted on an average 1450 tons daily during the month of May. This ore is entirely from the Calumet & Arizona and Superior & Pittsburg mines, at Bisbee, the C. & A. smelter doing no custom business. Much new work is being done, with large and important changes planned for the future. There are now five furnaces with a daily capacity of 300 tons each. The material is on the ground for a sixth furnace of 500 tons capacity, which will be erected in line with the others, and in order to make room for it the converters will be changed to the opposite side of the building. After the new furnace is in operation, it is planned to enlarge the old furnaces, which will be lengthened so as to have a daily capacity of 500 tons each. At present the mines of the two companies can not supply 3000 tons of good ore daily, the Oliver being the only one that could greatly increase its output. The management expects large new ore developments in the S. & P. mines, but there is not sufficient development work being done in these properties to warrant the expectation of a large increase in production.

New Power-Plant of the Copper Queen Mining Co.

The C. & A. is opening up in the Copper Giant, situated near Mammoth, in Pinal county, Arizona, a large amount of concentrating ore, which will eventually be handled at the Douglas smelter. When the smelting capacity is increased, the present system of handling the charge and feeding the furnaces will still be in use. The ore and coke are drawn from steel bins into charge barrows and the furnaces fed by hand. There are 24 steel bins, each with a capacity of 100 tons. Besides the ore in these bins, there is a reserve pile at the smelter of about 3000 tons, and a reserve pile of coke of about 7000 tons. The amount of material on hand and the methods of handling the smelter charges are in sharp contrast to those in use at the Copper Queen plant, the C. & A. employing hand labor, and the continuous operation of the furnaces being dependent upon the regular arrival of the ore trains from Bisbee. The Queen, on the other hand, raises its ore from the large orebeds by means of steam shovels. These dump it into cars drawn by electric motors. The cars pass under the limerock and coke bins, where the charge is completed, and is then run to the feed-floor and dumped directly into the furnaces. The supply of material on hand is always sufficient to keep the smelter in operation for a month without being replenished.

SALT LAKE, UTAH.

Tintic Stocks.—May Day.—Uncle Sam Consolidated.—Government Assay Office.—Ohio Copper.—Bingham Central Railway.

All records were smashed by the Salt Lake Stock & Mining Exchange last week in the volume of business transacted. Lively scenes were witnessed, and when the official report was issued it was found that 1,515,863 shares had been transferred, which represented a selling value of $936,047. Trading was confined largely to Tintic stocks, some of which made sensational fluctuations—the leaders being Sioux Consolidated and Iron Blossom. Phenomenal strikes have been made in both mines, and the owners believe an extension of the famous Colorado orebody has been uncovered.

Inclement weather has greatly handicapped construction work at the new Tintic smelter, and it is now practically certain that the first furnace will not be in commission until about July 1. The sampling mill, however, will be running next week. The first custom ore has arrived from outside camps, eleven carloads having been consigned from the Silver Shield mine, in Bingham. The May Day Mining Co. will pay a dividend of 1 cent per share, or $8000, on June 24, to all shareholders of record on the 20th. This company paid $64,000 last year.

The financial report submitted to the shareholders of the Uncle Sam Consolidated at the annual meeting held June 1 shows gross earnings to the amount of $135,455 during the fiscal year. There were mined and marketed 42,670 tons of ore, having a net value of $26.42 per ton. Dividends were paid to the amount of $70,000. The company began the year $9000 in debt and has ended it with about $1000 cash in the treasury. Ore shipments ceased last December, when the United States smelter was closed. The properties of the Sevier Consolidated Gold, Silver & Prospecting Co., near Kimberly, Utah, have been sold under an execution for $108,206. This corporation expended something over $225,000 in the purchase of property, equipment, and development, but the management was not guided by any technical advice in planning development or deciding on the character of mill-equipment needed. When the panic came on last autumn the company found itself financially embarrassed; whereupon, a receiver was appointed.

The passage by Congress of a bill, which has received the signature of President Roosevelt, to establish a Government assay office at Salt Lake has been hailed with satisfaction by Utah mining men. The appropriation made for the purpose stated is $29,500. The annual meeting of shareholders of the Ohio Copper Co., which was to have been held June 3, has been postponed thirty days, during which time it is said all details will be arranged relative to financing the enterprise. Advices from the East indicate that new people are interested, and that F. Augustus Heinze has agreed to sell a large portion of his holdings, retaining, however, 100,000 shares. It will take from 60 to 90 days to complete

the mill at Lark, the construction of which began before the financial upheaval of last year.

A Los Angeles syndicate has acquired a large tract of coal land near New Harmony, and has organized a company to develop and operate it. The scheme involves the construction of a railroad to be used as a feeder for the Salt Lake route. Within 30 or 40 miles from the coal is the Virgin City oil district, in which vigorous development is being prosecuted. Within the past week two producing wells were brought in, one capable of producing 30 and the other 50 bbl. per day. There are now four producing wells in the Virgin district, with good indications for others being drilled.

The ore and bullion settlements reported through Salt Lake banks last week amounted to $381,000. Ore shipments from the Park City district this week were 805 tons; the Daly Judge contributing 238 and Silver King Coalition 567 tons. The Independent Smelting Co. will resume the operation of the smelter near Ogden this week. Custom ores are now being received. The plant is equipped with one copper furnace. The Bingham Central railway, a Heinze enterprise, and which is being worked in connection with the Ohio Copper mine in Bingham, has begun condemnation proceedings against the Fortuna Mining Co. for a right of way across the property of the latter, through which it is necessary to drive a tunnel to reach the Ohio mine. The Bingham road is projected to carry on a freight and passenger business between Bingham and Salt Lake City; also to the mill and smelting centre at Garfield.

BUTTE, MONTANA.

Option on Butte-Montana.—Davis-Daly Estates.—Snowstorm Output.—Amador Fiasco.—Tramway Shaft.

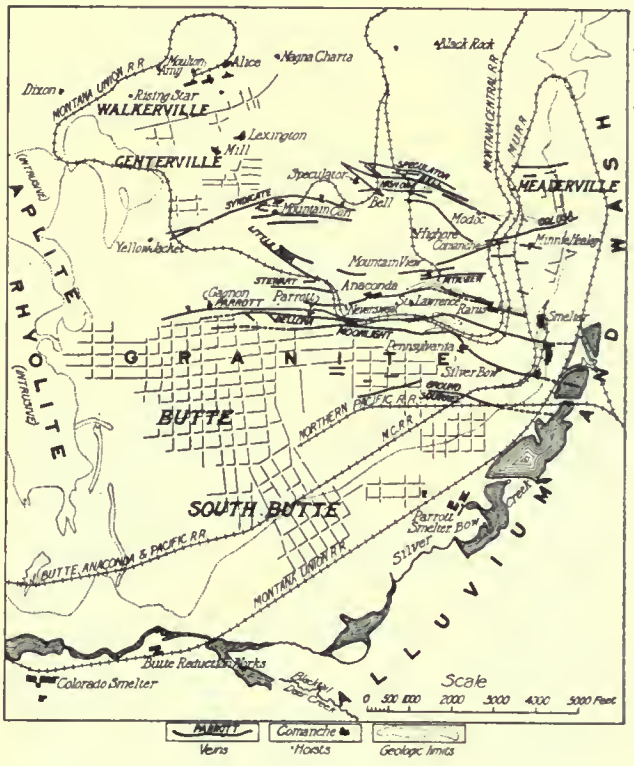
Recently a New York broker secured an option on a majority of the stock of the Butte-Montana Mining Co., which owns the Alex. Scott claim at Meaderville, adjoining the West Colusa of the Boston & Montana Co., and there are rumors current that he is acquiring the stock for the Amalgamated Copper Co. or for F. Augustus Heinze. The Butte-Montana Co. has been peddling its stock ever since it has been organized. The stock is selling at 30c. per share on the market, so it is evident that the option does not require the payment of much money. The Alex. Scott is being in a measure developed by the Boston & Montana Co., which is making connections through it with the West Colusa and Leonard for purposes of ventilation and safety. Under an arrangement with the Butte-Montana Co. it is sinking the shaft from the 700-ft. point to a depth of 1200 ft., and cross-cuts will be run from various levels to connect with the Boston & Montana workings. It is estimated that the Boston & Montana Co. will spend about $65,000 on the property, which is of direct benefit to the Butte-Montana, as it will develop the ground to a depth of 1200 ft. with no expense to the latter company.

Development is still going on in the Colorado mine by the Davis-Daly Estates Copper Co. A proposition has been advanced for reorganizing this company, but has never been acted on. The idea was a unique one. It was proposed to reorganize with a capital stock equal to the present capitalization and offer the new issue of stock in exchange for the present outstanding stock on a basis of one share of new for two shares of old stock. As there are outstanding about 750,000 shares of stock, that would return to the Davis-Daly treasury 325,000 shares. Having returned half their holdings to the treasury, the stockholders were to be given an opportunity to buy the stock back again, and put money in the treasury in place of the stock. The transaction would be equivalent to a heavy assessment.

Friends of F. Augustus Heinze who have returned from New York recently say there is little doubt that he will centre his activities here when he gets out of his financial and legal entanglements in New York. There is no gainsaying the fact that, notwithstanding his misfortunes, and the losses sustained by hundreds in Butte through him, Mr. Heinze still has many friends here, and it is possible that he could gather as large a political and personal following in Butte as he ever had.

Butte stockholders of the Snowstorm Mining Co. have received information indicating an early resumption of dividends. The mine is shipping 500 tons of ore per day, at an average cost of mining, it is claimed, of $1.06 per ton. The development work carried on during the shutdown greatly enhanced the value of the property, and it is now in condition to produce 1000 tons of ore per day without crowding.

According to reports from Chicago, the stockholders of the Amador Mining & Milling Co. have concluded that they were fleeced. The property is situated west of Missoula, Mont., and the flotation of the company was spectacular. Stock to the amount of $350,000 was sold and the money used for the construction of a railroad from the mine to the Northern Pacific track and for the erection of a $60,000 smelter before the mine was developed to a producing stage or its value at all demonstrated. In all, five cars of ore



Map of Butte District.

have been shipped from the mine, that did not pay treating charges. The company was organized about five or six years ago by D. E. McKinnon, a lawyer from Yakima, Wash., and capitalized for 2,000,000 shares at $5 par. It owns about 50 mining claims, a townsite, and railroad 10 miles long, built at a cost of $160,000, and a worthless smelting plant.

The Butte & Buxton Mining Co. is cleaning up the old workings preparatory to extensive operations. From a number of samples copper assays of 14 to 23% have been obtained, in addition to 11% lead, 40c. in gold, and 24 oz. silver per ton. The deepest working is about 150 ft. The company will sink several hundred feet at once.

The Butte Coalition Co. is shipping 1000 to 1100 tons of ore daily, mostly coming from the Rarus mine. It is asserted that the company is marketing its copper under a total cost of less than 8½c. per pound.

The new shaft of the Tramway mine, being sunk jointly by the Butte Coalition Co. and Butte & Boston Co., is down 1800 ft., which corresponds with the 1500-ft. level of the Minnie Healey, with which mine the Tramway shaft is being connected; however, the lowest present working of the Minnie Healey is 1100 ft. On the latter level the big orebodies recently talked about a great deal were opened last fall before the shut-down, and are not being worked at present.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

To remove rust from steel, immerse the article to be cleaned in a strong solution of cyanide of potassium, mix to the consistence of thick cream a paste of cyanide of potassium, castile soap, milk of lime, and water, and after immersion brush the steel briskly, using the paste.

Water-proofing for canvas which will leave the material soft and flexible may be made by boiling 1 lb. laundry soap in 6 pints water, and adding while hot 112 lb. white lead. Another good water-proofing for canvas and 'slickers' is made by boiling together 1 lb. flour of sulphur and 1 gal. linseed oil.

Cost of power per horse-power year, developed electrically by turbine water-wheels, ranges from $6 to $23 at various Eastern plants. It is sold at $13 at Niagara; at Lawrence, Massachusetts, it costs about $20, with a 1000-hp. installation. The average cost of steam-power would not exceed 0.8c. per horse-power hour.

Bituminous coals, as well as lignites and peat, will produce on an average 2.4 to 3 times as much power if used for the production of gas instead of steam. Another important item in the same connection is that low-grade coals which will not burn under boilers are capable of producing work by direct gasification in producers.

Gold precipitated on the fine particles of zinc detached when packing or cleaning the zinc-boxes in a cyanide plant may be almost wholly trapped by passing the overflow from the zinc-box through a compartment filled with 'excelsior'. The excelsior may be incinerated and the ashes mixed with the 'gold-slime' or precipitate for melting.

The first re-enforced concrete building in this country, and probably in the world, was erected in 1875 by W. E. Ward, near Rochester, New York. "Not only all the external and internal walls, cornices, and towers were constructed of concrete, but all of the beams and roofs were exclusively made of concrete re-enforced by light iron beams and rods."

The location survey for a placer claim or a mill-site does not differ from an ordinary land survey to establish boundaries. The corners are like those of lode claims, and are marked with the name of the placer or mill-site, and the number of the corner, on the side toward the claim. The tie-lines to reference monuments are also the same as in the lode claims.

Cement-making materials, namely, limestones with an admixture of clay or finely ground shale, usually in the proportion of three parts by weight of limestone to one part of clay, must be so proportioned as to bring the $CaCO_3$ in the 'mix' to about 76%, Al_2O_3 to about 5%, Fe_2O_3 to 2%, SiO_2 to 13%, and $MgCO_3$ not over 2%. Such a 'mix' will make a first-class portland cement.

Assay-values of gold ores as returned on British assay reports are given in grains, pennyweights, and ounces. The British habit in making approximate mental calculations from assays so stated is to take each grain of gold as representing 2d., each pennyweight 2s., and each ounce £4. An ounce of gold is actually worth approximately 85s., which would give a value of 2.125d. per grain.

Sale of an unpatented mining claim for taxes carries only the locator's title. To protect the title obtained through a tax sale, the purchaser at such sale must perform the annual work. If annual work is not performed and the claim is properly re-located, the re-locator will hold the claim as against the purchaser at a prior tax sale. He would also hold the fixed improvements found on the claim at the time of the re-location.

'Pitch', as used in relation to ore deposits, is the angle which the longitudinal axis of an ore-shoot makes with the direction of the dip of the vein. Similarly, it is used to denote the direction of movement of one or the other wall in faulting. 'Throw' is the vertical component, 'heave' is the horizontal displacement, and 'pitch' is the angle of divergence from the dip which the line of movement of the down-throwing wall has made.

Pitted gold bullion bars result usually from adding an excess of nitre and not leaving the 'melt' long enough in the furnace to permit the gases generated to escape. When oil or grease is used in the mold to prevent the bar sticking fast, gases evolved from these substances will also pit or roughen the surface of the bar. The best coating is produced by swabbing the heated mold with a lime-wash of the consistence of cream, just before pouring.

Phonolite is a rare rock, not occurring in many places in the United States, the most noted examples being at Cripple Creek, Colorado, where it exists as dikes through the older granite and breccia, and in the Black Hills, South Dakota, where the dikes cut through the Cambrian sedimentaries. The term signifies 'sound-stone' or 'clink-stone,' as it was originally called in England, because of the metallic ring which it gives on being struck. Many rocks, especially close-grained rhyolites, possess the same quality, but the name phonolite does not cover all those which ring, as 'porphyry' applies to all rocks which have crystals conspicuously developed in a groundmass of crystalline or sub-crystalline texture. It is a specific name for a compact, gray to brown, mixture of the glassy variety of orthoclase known as sanidine, and nepheline, with some hauyne and other accessory minerals in small quantities, but quartz is absent. It has a tendency to split into thin slabs and plates, sometimes suitable for roofing purposes. It decomposes readily, becoming rough and pitted, resembling ordinary trachyte, to which it is closely related.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

A Theory of Ore Deposition.

The Editor:

Sir—The discussion of the subject of ore-deposition which has recently appeared in the MINING AND SCIENTIFIC PRESS has interested and entertained many readers, and inspires me with the belief that there is room for one more opinion. There is a tendency to assume the presence of water in intrusive igneous rocks, without an attempt to give any explanation of how it got there. In order to offer an explanation of how the presence of water may be accounted for in the interior magma of the earth it is necessary to assume that the planet was at one time in an incandescent condition, in which state it was so hot that all the materials composing it were rendered gaseous. While in this gaseous condition it was subject to all the laws of diffusion of gases.

According to the law of the diffusion of gases credited to Dalton, in a mixed body of gases each gas diffuses uniformly through the space occupied. Therefore all the gases composing the earth-sun, including water-gas, diffused uniformly through the mass from centre to circumference. As cooling caused a crust to form there remained, below the point of critical temperature, a complex magma in which water-gas is associated with all the other elements that are actually or potentially in a gaseous condition. As pressure increases the fusing temperature it is probable that the melting point and the critical temperature or absolute boiling point become the same. Owing to the higher melting point due to pressure there is probably no liquid material near the surface, nor at any point below the critical temperature of all matter, which would be reached at a depth of about 100 miles. The zone of flowage, which extends from the zone of fracture to the zone of critical temperature, is that zone in which all magma moves under pressure like wax and closes all openings of whatever nature.

If, as stated, the zone of critical temperature of all matter is reached at a depth of 100 miles, there is still remaining a sphere of 7700 miles diameter in which the water-gas is diffused as in the original earth-sun. By the process of secular cooling the materials that form solids at high temperature add to the thickness of the zone of flowage, and this liberates the water gas and all other gases associated with the original gaseous complex magma. After being liberated from their associated material these gases diffuse through the zone of flowage, up against the zone of fracture, and accumulate beneath natural vents, such as fault-planes and volcanoes.

When sufficient steam and other gases have accumulated to cause the rock to be super-saturated and highly elastic and vesicular, an old fault-plane is re-opened or a new one created, into which the steam and gases rush with tremendous pressure. The colder rocks of the walls of the fault-plane in all its ramifications present a large surface of lower temperature than the steam, and the consequence is sudden condensation, followed by closing of the fault-plane. This is the characteristic movement of an earthquake, and is repeated as often as the supply of accumulated steam lasts in the super-saturated magma below the zone of fracture. The super-saturated magma is carried along by the expansive force of the enclosed steam and penetrates the fault-plane as a dike. The combination of effects produced is the result of slow diffusion of water-gas and other gases through the zone of flowage resulting in local super-saturation of the magma below the zone of fracture at points where previous accumulations of the same nature have elevated the temperature and rendered it possible for steam above the critical temperature of water to get nearest the surface. If the steam has sufficient expansive force, it may issue at the surface as a hot spring, a geyser, or a volcano, and may carry with it a portion of the super-saturated magma and discharge it as liquid lava, or in extreme cases atomize it as volcanic dust. All of these phenomena are the results of a common cause and only indicate different degrees of intensity. The dike may never reach the surface in a fluid condition, and may be exposed by erosion in a subsequent geological age. A single irruption may be insufficient to carry the dike far into the fault-plane, and indeed it seems probable that many such earthquakes, each accompanied by a farther and farther penetration of the super-saturated magma, occur along a single fault-plant. With such a great store of steam in the interior magma, it is plain that wonderful effects will be produced by the gradual liberation which is due primarily to secular cooling. Such igneous intrusions as cause regional elevations without breaking through and overflowing on the surface are called laccoliths, and in some cases are of immense size. The Henry Mountains, in Utah, described by Gilbert, and the Black Hills, in Dakota, are familiar instances of this character.

The internal topography of the zone of fracture probably resembles the external topography, and causes the upward flow of steam to drain by diffusion toward well established vents, in the same manner but reversed action as the surface drainage conducts water to sinkholes in some limestone countries.

Having outlined what I believe to be the prime cause of all movements in the earth's crust, I now return to the question of ore-deposition. It has long been suspected that igneous rocks had something to do with ore deposition, and, in fact, as soon as ore is discovered in a new region the prospector begins to show its merits and relation to the nearest known igneous rocks.

It appears from the foregoing argument of the steam carrying forward the intrusive dike, that the presence of dikes in the vicinity of ore is as natural as it is frequent; and that ore is deposited from hot solutions resulting from the condensation of the steam that brought the dike up into the fault-plane. The dike may be the older, or it may be the result of a later and more violent intrusion of steam after the main part of the ore has been deposited. The dike is not the cause of the ore, any more than the ore

is the cause of the dike, but the two have a common origin, and the ore is the result of chemical action of the steam and other gases on the magma from which the dike was derived. After being dissociated from the gaseous magma, the steam is forced upward by the difference in specific gravity between it and the material of the zone of flowage. As to the effect of the associated gases, we have to consider that according to the original hypothesis all the gases that composed the earth-sun were present and diffused through the magma in the same manner as the steam or water gas. The gases which are known to be associated with steam in violent explosions are chlorine, hydrochloric acid, boron, hydrogen bi-sulphide, hydrogen, nitrogen, hydrocarbons, sulphur di-oxide, and carbonic acid. Some of these assist in solution of the metals, and others act as precipitating agents when the solutions have come near enough to the surface to cause the temperature to fall. It will be seen that a radical reduction of temperature is necessary for deposition, and this is probably the reason why mines do not grow richer with depth, in agreement with the popular idea and the prospectus. Hydrocarbons associated with mineral solutions are probably the cause of the precipitation of gold and silver and copper in a metallic state, where it is plain that they are not the result of secondary enrichment. As regards the general interest in this subject, I think that most men who have to do with mining and the treatment of ores have some theories on the subject, which they have arrived at, they hardly know how, and to which they cling with a constrictor-like obstinacy worthy of a better cause. A good many technical men are instinctively opposed to any idea not orthodox to the point of dry rot, and resist the introduction of heresy with heroic fortitude. A few of them would require a surgical operation to get a new idea on the subject unless it was proposed by some pundit who probably never entered a mine. On the other hand, it would require a deep incision to inoculate some of us with the theories proposed by some of the accepted authorities.

HIRAM W. HIXON.

Philadelphia, May 4.

A Protest.

The Editor:

Sir—I was considerably interested in the article 'From Mine to Battleship' in your issue of May 9, and find that there are a number of improvements in the desilverization of lead since the time when I was interested in lead smelting. I am writing, however, to protest against the abbreviation used for the symbol for acetic acid in the equations representing the transformation of lead into white lead. Coming from the pen of the editor of a journal that prides itself on its technical language, it cannot be overlooked, and I feel sure the writer of that article is the last person to wish that it should be. I am aware that a number of text-books, and good text-books, use these abbreviations, which is all the more reason for discouraging them. Thus we find chemical equations in which ammonia is expressed as Am, and cyanogen as Cy; the latter is most idiotic, as it contains the same number of letters as the proper symbol CN. So long as those radicals go in and out of combination like an elementary body, these abbreviations may serve, but directly the reaction is of such a disturbing character as to split them up into their elementary components, then an equation with an abbreviated symbol conveys no meaning. Take as a simple example, the equation expressing the reaction which occurs when concentrated sulphuric acid is added to dry crystallized potassium ferrocyanide.

$$K_4Fe(CN)_6 + 6H_2SO_4 + 6H_2O = 2K_2SO_4 + FeSO_4 + 3(NH_4)_2SO_4 + 6CO.$$

Here we at once see how each substance is broken up and re-combined and the equation balances. If we use the abbreviated symbols the equation will read:

$$K_4FeCy_6 + 6H_2SO_4 + 6Ag = 6CO + 2K_2SO_4 + FeSO_4 + 3Am_2SO_4.$$

Here we find symbols Cy, Ag, and Am on one side of the equation and not on the other, and the equation does not balance. Chemical equations have sufficient unavoidable stumbling blocks for the student without introducing unnecessary ones. As an example, take the foregoing equation and compare it with the equation which represents the reaction that takes place when sulphuric acid diluted with water is added to a water solution of ferro-cyanide of potassium:

$$2K_4Fe(CN)_6 + 3H_2SO_4 = K_2Fe_2(CN)_6 + 6HCN + 3K_2SO_4.$$

Note when concentrated acid and dry salt are used H_2O plays a part in the equation, and when acid diluted with water is added to a water solution of the salt it does not. Of course it is easily explained, but it is puzzling to the beginner.

[The exception is well taken.—EDITOR.]

Electric Furnace in Zinc Smelting.

The Editor:

Sir—I desire to bring to the attention of your readers, particularly those in the Western States living near cheap electric power, and those producing zinc ores, a subject of vital importance, namely, the possibilities of the electric furnace adapted to zinc smelting. The electric furnace is a comparatively new thing, commercially at least. It is only a matter of a few years since electricity has been applied metallurgically. Without the electric furnace, the alkali metals and aluminum would not be cheap commodities; and such valuable materials as carborundum, ferro-silicon, vanadium-manganese, etc., calcium carbide, boron carbide, etc., would be unheard of. While many have endeavored to produce zinc by electrolysis, the method has not yet proved satisfactory from the standpoint of dollars and cents, although zinc can be deposited electrolytically under proper circumstances.

Taking my own experience with the resistance of electric currents passing through metals and graph-

ite as a criterion, I propheey that zine ean and will be produeed eommereially in an eleetrie furnaee. I find a remarkable uniformity in the heat produeed by resistanee. Take niekel wire, for example; its resistanee is very high; niekel is strong, tough, not readily affeeted by heat, durable, has a high melting point, and ean be drawn into a wire which is uniform. A small resistance-furnaee made with niekel wire gives uniform temperatures, and what ean be done with a small furnaee, I believe ean be done in a large one with still greater uniformity. Moreover, the shape of a furnaee could be made to suit almost any eondition, there being no need to arrange for grates, eombustion-chambers, or staeks, like the ordinary zine-furnaee. Besides this advantage, eeonomy of heat lost by radiation, small spaee required, eeonomy of redueing material in the furnaee-charge, and greater eomfort for the workmen are advantages to be considered. The electrie pyrometer or galvanometer would indicate instantly the temperature of the furnaee, and the eontrol of the temperature would be almost as readily fixed as the indication of temperature. The present gas-fired, or the older eoal-fired furnaee, requires skilled furnaee-men and judgment in gaining the proper heat. If too hot, it takes considerable time to adjust the heat, and if too eold, it takes even longer to fire up. With an electric furnaee, all that is neeessary is to regulate the current a little and the furnaee responds in a few minutes.

An eleetrie furnaee could be designed whereby the problems of eharging, smelting, and removing the retort-residues could be redueed to a minimum of labor, owing to its compaet shape and freedom from the necessity of constructing grates, etc. I believe it is the duty of every mining man who is near to ore and power to investigate this proposition, and I suggest that these men experiment and perfeet this process, either by themselves or by pooling their interests.

Hercules, California, May 16.

Bogus Promoters.

The Editor:

Sir—As an old subscriber of your paper I trust that you will allow me a small space in which to make some remarks eoncerning the various so-called promoters infesting Mexico at the present time. It is certainly strange that sensible and successful business men from all parts of the United States and from Europe, should be such dupes when face to face with some well dressed individual giving a beautiful highly tinted pieture of the wonderful mine or mines he is bent upon selling. Some time ago, all these mines were copper properties, now they are gold; metals change even as prices do on Wall Street, and now 75% of such mining in the hotel of Mexico City is gold, and especially 'placer.' By the way, I was informed that a placer had been loeated here that ran $40 per eubic metre. Of course, being told such Arabian Nights tales in a fashionable hotel, one must grip his ehair and smile, but it certainly outshines anything that Humboldt or our loeal papers, with all their vivid imagination, dare to dream of; yet, business men day after day are induced to part with hundreds of dollars to grafters, and often take long and hard journeys to see alleged wonders, and return cursing mines in particular and mining men in general, never realizing that all their loss and trouble were due to giving ear and eredit to a perfect stranger in a strange hotel in a foreign land, in whieh, moveover, they are more than strangers, being in many instances ignorant of the language, and above all, of the character of the people.

This absolute stealing of money by means of spurious tales and unserupulous lying is not practised entirely among the visitors, but even among resident engineers and investors. Only a few days ago, I was with two other experts in the State of Michoacan, and we were accompanied part of the way by a well known mining engineer and expert, a man of means and influence, and being well known to us, he mentioned his reason for his journey, and when he had finished, I and another coolly informed him that he was on a wild-goose chase, sinee we had each at different times been interested in the mine by the same grafter. To my own certain knowledge, this person had obtained money from several people at different times for pretended locations or inspections, which he had never made and had no right to make, and more than one engineer had made the journey to see the mine, and had never seen it, for the simple reason that the given directions required about three days' journey from the actual spot; yet this rogue has been receiving money from people for his information and bogus inspections.

There is no need for investors to be caught or to buy gold-bricks here in Mexico. If they would only give the same attention to the promoter, and exercise the like caution as they must do in their several businesses at home, they would get good properties, not bonanzas, nor properties containing the romantic wealth described by Humboldt, but a good return for their money; they would prevent Mexico from being looked upon as a well into which the stranger is expected to drop his money; and this will be brought about when the would-be investor consults with known and reliable mining men, and gives the hotel lobby hunters a much deserved snubbing.

Mexico City, May 1.

Surface Enrichment in Sonora.

The Editor:

Sir—After extensive observation of the mineral deposits of Sonora one is led to the eonclusion that some parts of this eountry are notable for the richness of the surface ores as eompared with those eneountered at moderate depths. The writer does not, by this statement, intend to convey the impression that many of the orebodies become commercially worthless at a moderate depth, but it is true that, in many eases, as development progresses, the assay-value becomes redueed and often the discovery of rich ore at the surface has led operators to install metallurgical plants that have soon become useless on aeeount of a radieal change in the ore. In free-milling gold veins sulphides often appear at a few

hundred feet of depth and totally change the metallurgical conditions.

In many regions which produce copper it has been found that this metal has been leached out at the surface and concentrated at a lower level; but in northern Sonora there are myriads of copper deposits in which the surface ores are rich, while at a depth of from 200 to 400 ft. the primary ore is reached with only a shallow zone of secondary sulphide enrichment intervening.

The surface ores are largely silicates. Varieties of dioptase predominate and yield frequently assays of 25 to 45% copper. Carbonates are relatively rare. The primary ore is generally iron pyrite containing from 2 to 6% copper, and the cleavages are usually coated with a film of secondary chalcopyrite. The practical miner and the promoter generally assume that this yellow mineral is pure chalcopyrite and base their calculations on a copper content of over 30%, much to the detriment of the ignorant investors who are attracted by their statements. In silver mines also, ores are encountered near the surface rich in native silver, horn silver, and tetrahedrite.

Two features are therefore especially notable here in respect to copper, gold, and silver: (a) that the zone of alteration is comparatively shallow; (b) that the surface ore is often extremely rich.

Since the superficial changes in orebodies are especially dependent on the action of the surface waters, we are led to consider what relation these local phenomena have to the Sonora climate. The rainfall of northern Sonora is well known to be very light. Carefully kept records are lacking, but the average precipitation at Tucson, Arizona, for 11 years was but 11 in. per year, the minimum being less than 8 in. On the other hand, the annual evaporation is upward of 60 in. It is reasonable therefore to attribute the shallowness of the alteration to the lack of water and the richness of the surface ore to lack of erosion.

The chemical actions and reactions and the exact physical conditions by which gold and silver are concentrated in surface rock are not fully known. The formation of the rich silicate ores of copper may well be due to the action of circulating waters, since the descending waters carry carbonic acid rather than silica. This is well shown by the abundant formation of the calcareous deposit known as *caliche*, its lime being in many places chiefly derived from the feldspars of volcanic rocks by the solvent action of atmospheric water. Of course, to these generalizations, there may be many exceptions. There are in Sonora, gossans underlain by commercial ores and there are many barren gossans that have never been explored. Further, in some mines relatively rich ores have persisted to a substantial depth. At La Sultana good ore is found to a depth of 1000 ft. or more. At Minas Prietas secondary enrichment has persisted to the lower levels in the rhyolite, though in the underlying granite ore is lacking. At Cananea some of the gossans covered good ore. These conditions, however, seem to be exceptional rather than regular, for this region, and may be due to special local causes, which can be determined by careful study. A fact of interest, frequently observed in Sonora, is that sulphides often occur far above the permanent water-level. This in turn must be attributed to the limited action of the surface water, which is usually the most active agent in oxidation.

It will be of interest to compare notes on these points with other observers in arid regions, and possibly some rules of the relation of climate to secondary enrichment in ore deposits may be established for the guidance of prospectors.

Cyanide Costs.

The Editor:

Sir—In view of the fact that the precipitation and clean-up costs at various cyanide plants have been recently published, the following summary of these costs at the Liberty Bell mill may be of interest. The figures are for the month of March, 1908, and therefore represent present practice; they are complete only as to labor, supplies, and power, and do not include the distributed charges of heating, lighting, superintendence, and depreciation.

Ore milled (tons of 2000 lb.)	10,548
Solution through zinc-boxes (tons)	24,510
Precipitate recovered, washed and dried (lb.)	1,275.5
Bullion from same (oz.)	16,016.8
Metal in precipitate (per cent)	86.1
Bullion fineness (gold and silver per 1000)	950

COSTS.

PRECIPITATION.		
Zinc, 4700 lb. at 8.97c. per lb.	$421.60	
Cutting	65.00	
Labor	81.55	
Power and supplies	26.65	
		594.80
CLEAN-UP AND FILTER-PRESSING.		
Labor of cleaning and re-packing boxes, and de-watering precipitate (There are 12 five-compartment boxes, each compartment having 20 cu. ft. of zinc space.)		43.50
REFINING.		
Acid treatment and washing.		
1050 lb. sulphuric acid at 4.6c. per lb.	$ 48.30	
Labor	55.30	
Power and repairs	8.45	
	$ 112.05	
Drying and melting.		
Coal, 750 lb. at $6 per ton	$ 2.25	
Coke, 2500 lb. at $17 per ton	21.25	
Flux	32.75	
Crucibles	36.00	
Labor	29.00	
Repairs and sundries	3.05	
	$ 124.30	$ 236.35
Total cost		$874.65

COST PER TON OF SOLUTION.	
Precipitation	$0.0243
Clean-up and filter-pressing	0.0018
Refining	0.0096
Total	$0.0357
Refining cost per Troy ounce of bullion	$0.0148

W. A. MOULTON.

Telluride, Colorado, May 1.

RECENT WORK ON THE COMSTOCK.

Written for the MINING AND SCIENTIFIC PRESS
By WALTER D. O'BRIEN.

The drainage of the Comstock mines twenty-five years ago was accomplished by a pumping plant the moving parts of which weighed 6,496,400 lb. This enormous weight was raised and lowered 10 ft. nine times per minute. In the Cornish system of pumps then in use 2.7 miles of pump-rod were employed, which, with the balance-bobs, pumps, and moving parts, actually weighed 2230 lb. for every gallon of water raised. A train of cars nearly a mile long would be required to transport this machinery. Can one then wonder that when this stupendous plant was found inadequate, pumping ceased and the mines were allowed to fill with water?

The abandoned pumps, not including foundations, installation, or freight, cost about $1,300,000. Their maximum pumping capacity all told was less than 5400 gal. per min., raised to an average height of 1152 ft. The cost of operating this plant was about $58,120 per month, or $697,440 per year. This did not include the cost of broken parts, but represented daily operating expenses for pumping alone. One would think that such a plant could pump the ocean dry, but it could not handle the water of the Comstock lode. The old records show that in almost every instance where any extensive prospecting work was tried on the lower levels, heavy flows of water were encountered.

In February, 1882, a heavy flow of water from the 2810-ft. level of the Exchequer mine, estimated at 120 miner's inches, flooded the lower levels. The pumps were run to their full capacity, but the water still rose, and not being able with pumps and bailing tanks to control it, all pumping operations were stopped for good on March 28, 1882.

At the time the lower levels were abandoned, the pumps were daily discharging about 4,000,000 gal. hot water (in some places the water was, and still is, 160° F) to the Sutro Tunnel level. The expense of these operations, under the then existing conditions, was enormous, so that finally one company after another withdrew its financial support, and the greatest of all gold and silver mines were practically abandoned, until the Comstock Pumping Association was organized in 1898.

This association was originally composed of 24 mining companies, and each company agreed to defray its percentage of the expense of unwatering the mines. The water then stood a few feet below the Sutro Tunnel level; in fact, some of the South End mines were then overflowing into the south lateral of the Sutro Tunnel.

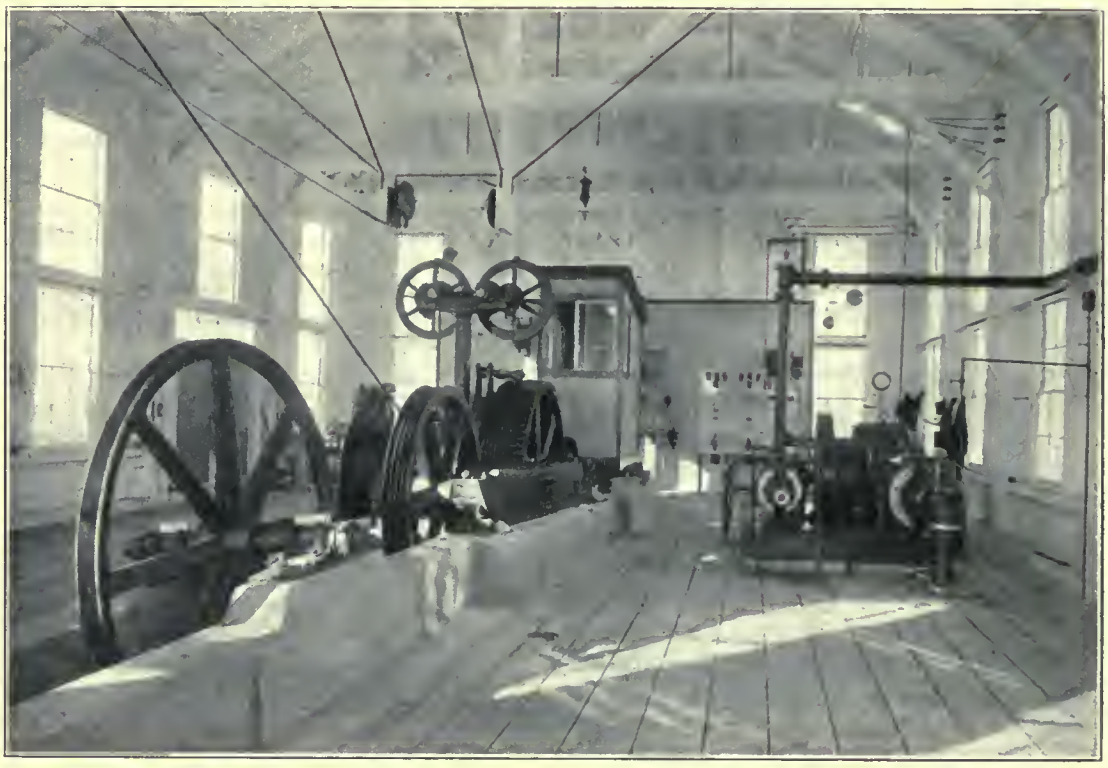

Fig. 2. Hoisting Plant at Union Shaft.

The old superintendents who had charge of the mines previous to 1886 made extensive reports on the conditions and the amount of ore in reserve before the mines were closed down. These reports showed that $600,000,000 had been extracted from the Comstock lode, and that the lower levels had not been thoroughly prospected, on account of the flow of water. In many instances known bodies of good milling ore were left in the old workings.

The best engineers in the country were then employed to devise ways and means of unwatering the mines and to design and equip the mines with the most modern pumping plants. For nine years the Pumping Association has kept alive the old mines, and the fruits of its past efforts should be realized from one to three years hence.

Instead of trying to open each of the old shafts, groups of the companies combined to repair and operate through common shafts. The shafts that drain the different mines are the C. & C. shaft and the

Ward shaft. The Union shaft is also below the Sutro Tunnel. The mines are now drained to the 2550-ft. level of the Ward, 2450-ft. level in the C. & C., and the 2450-ft. level of the Union shaft.

By the use of hydraulic elevators, the water in the C. & C. shaft was lowered from the Sutro Tunnel level to the 2150-ft. level, it having required 200 miner's inches under a pressure of 900 lb. per sq. in. to accomplish this feat. On the 2150 level of this shaft three $6^{11}/_{16}$ by 24 in. Riedler pumps have been installed. Fig. 1 shows these pumps in place. The station containing the pumps is 20 by 20 by 119 ft. in the clear. The timbers are 14 by 14 in. and lagged. These pumps have a capacity of 4500 gal. per min. and are operated by means of three 200-hp. Westinghouse induction motors. They handle all the water in the North End mines, lifting the water from the 2150 level to the 1650 or Sutro Tunnel level, through which it is discharged.

By the use of hydraulic pumps, the water has been lowered to the 2475-ft. level, where there is installed a hydraulic pump that makes one lift of 3000 gal. per min. to the electric Riedler pumps on the 2150 level. For operating this pump 1400 gal. per min. pressure water is used, under a pressure of 1100 lb. per square inch.

On the 2400-ft. level of the Ward shaft there is an electric pump, operated by means of a 200-hp. motor at 1720 rev. per min., that makes one lift of 900 ft. to the Sutro Tunnel level, pumping 600 gal. per min.

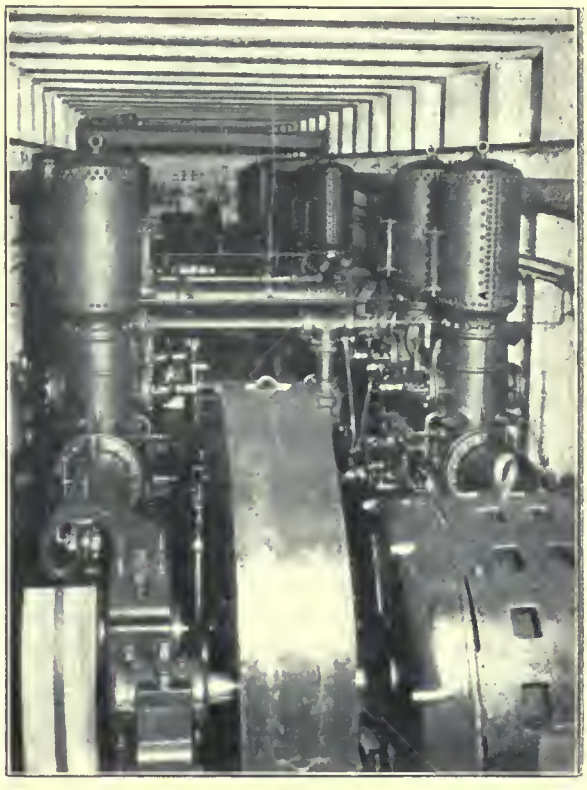

Fig. 1. Riedler Pumps, at the 2150 ft. Station of the C. & C. Shaft. Capacity 4500 Gal. per Minute.

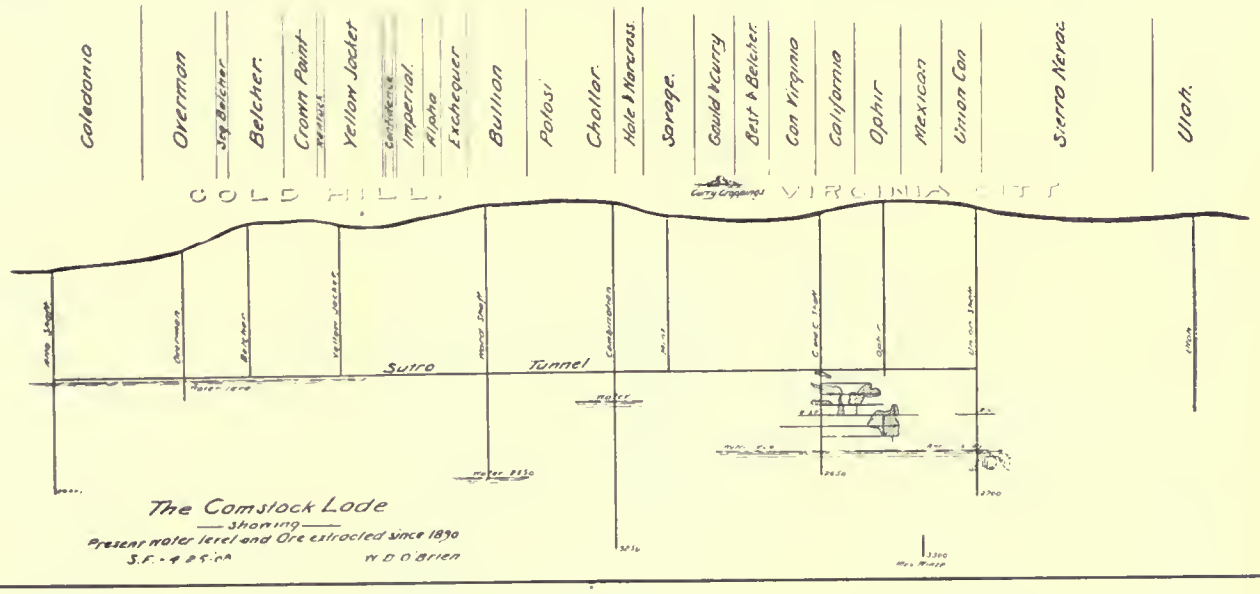


On the 2475-ft. level of this shaft the finest electrically driven pumping plant in the world is now being installed. The capacity of this one unit of the ultimate system is 1650 gal. per min. The mine will be equipped with this unit to sink to the 3100-ft. level, where a second unit will be installed.

The cost of this new pumping system, not including installation, was about $200,000, this price covering the two new units on hand and to be installed in the Ward shaft. Compare this cost with $1,300,000, the cost of the antiquated pumping plants. The capacity of the old installation was about 5,000,000 gal. daily, as against 9,000,000 gal., the capacity of the new installation.

The following gives an itemized list of the present monthly expenditures and costs of operating the pumps to unwater the mines on the Comstock lode:

C. & C. SHAFT.

Electric power	$2360
Water power	2200
Labor	900
Labor changing throats	25
Repairs and renewals	400
Oil waste, etc.	100
Compressed air	100
	$6085

WARD SHAFT.

Electric power for pumps	$1125
Electric power for compressor	400
Labor	660
Repairs, etc.	100
Oil waste, etc.	75
	$2360

The total monthly cost of pumping is, therefore, about $8445, as against $58,120, the former monthly expense of operating the abandoned pumping system, of less than half the capacity of the new, which makes a saving of $596,100 per year. The present pumps also save from $50,000 to $100,000 on repairs and new parts not included in the above saving.

A hoisting plant recently installed in the Union shaft is shown in Fig. 2. It is operated by means of a 100-hp. General Electric motor. This hoist handles 20 tons an hour from the 2000-ft. level, at a cost of about 3 cents per ton for power. This does not include expense of engineering or mining. The hoist uses a continuous cable with two cages. A similar hoist is installed at the C. & C. shaft and is set up back of the old steam hoist now in use.

The accompanying tabulated statement gives a list of the shafts that have been opened up below the Sutro Tunnel level and the orebodies extracted since the organization of the Comstock Pumping Association. Outside of the Consolidated Virginia, Ophir, Mexican, and Union, there has been little or no development work done below the Sutro Tunnel since the unwatering of the Comstock. When the new pump is installed on the 2475-ft. level of the Ward shaft, connections can be made with the Combination shaft and the mines can then be drained and explored to a depth of 3100 ft. with good ventilation.

From the foregoing, it can be readily seen that the management of the Comstock mines, through the Comstock Pumping Association, has in the past nine years done everything in its power to install the most up-to-date mining machinery, and has equipped the mines with plants that will permit of the exploration, thorough prospecting, and development of the lower levels. Whether or not the miners will again find large bodies of rich ore remains to be seen.

A method of raising oil from deep wells has recently been developed by Bruno Leinweber, of Vienna, Austria. The essential feature is an endless absorbent band hanging in the well, the lower loop immersed in the oil. At the top of the well the band passes between a pair of rollers, which squeeze the oil from it. The band is made of flat hempen rope, faced with an absorbent fabric having a long nap. This device has been tried experimentally in a well 1700 ft. deep by 9 in. diam., using a band 3 in. wide and 0.3 in. thick, having a facing 2½ in. wide and 0.8 in. thick. The hoisting mechanism imparted a speed of 8 in. per second to the band. In spite of this slow speed, and other imperfections in the details of the machine, the oil was raised at the rate of 0.85 lb. per yard of band-length. It is claimed for the device that it may be used to depths of 5000 ft., in either vertical or inclined bores, and is applicable for lifting the heaviest and thickest oils, as well as those containing paraffine and sand.

Molybdenum may be determined qualitatively by adding H_2O_2 to concentrated solutions, followed by a little excess of NH_4OH, producing a brownish red color. The color is discharged by large excess of NH_4OH or by dilution. A perceptible reaction was observed with 0.001 mg. MoO_3.

ACCUMULATION AND ABSORPTION OF GOLD AMALGAM BY COPPER PLATES.

In the bulletin of the Institution of Mining & Metallurgy, Edward Halse gives the results of experiments showing that actual absorption of gold into the copper is practically a negligible quantity, in no case exceeding a fraction of a grain to the ton of ore milled. A separate paper on the same subject by W. F. A. Thomae expresses a judgment in full accord with this, setting the limit of absorption at not more than 10 oz. to a plate 4 ft. 6 in. by 12 ft. The experience of Arthur L. Collins at the Hidden Treasure mill, at Black Hawk, Colorado, is recalled, where plates in use 10 years yielded 8 oz. fine gold after being thoroughly scoured. It is pointed out that a copper plate will absorb mercury to saturation, which point is reached at about 1%, in approximately 16 days. The gold, instead of penetrating the copper, tends to accumulate in the form of hard scale upon its surface. The effect of silver-plating is to restrain absorption at first, since the mercury has to diffuse through the silver, but eventually the absorption reaches saturation as in the case of plain copper. The rate and amount of accumulation of hard scale varies extremely under different conditions. Comparisons between long-continued observation on this point at the Drumlummon mill, in Montana, and at the Sucre mill, in Colombia, show such wide discrepancies as 0.499 and 1.721 dwt. fine gold per ton of ore milled at the two places through periods of about two years. The gold recovered by regular clean-ups at these two mills was respectively 4.65 and 9.49 dwt. per ton of ore. The rate of accumulation roughly follows the grade of the ore, and it is found, as might have been expected, that the proportion of silver present materially affects the rapidity with which the scale will form.

Building operations in 1907 in the United States show a decrease over those of 1906, but an increase over all previous records, according to a recently issued report of the U. S. Geological Survey. The total cost of the buildings erected in the principal cities of the United States in 1907 was $661,076,286, a net decrease of $17,634,683, or 2.6% from the figures of 1906, but an increase of 2.55% over those for 1905, and 40.86% over 1904. The unit cost of building, however, increased in the past year. In the cities showing a decrease in building, New York takes the lead with a falling-off of $41,591,982, or 26.84%; St. Louis is next with $8,045,526, or 26.87%; Chicago next with $5,616,245, or 8.68%, and Brooklyn last with only $149,304, or 0.21%. Naturally, San Francisco leads the list in the increased building operations. The total number of building permits issued during 1907 was 12,126, for buildings to cost $91,502,240, an increase of 162% over the building in 1906. In 1905, before the fire, the cost of building operations was only $18,268,753.—*Engineering News.*

To anneal the core of an electro-magnet, first heat it to a low red and cool in soft soap: then reheat it to the same point and allow it to cool while covered in slaked lime.

ROUND MOUNTAIN, NEVADA.

Written for the MINING AND SCIENTIFIC PRESS
By GEORGE A. PACKARD.

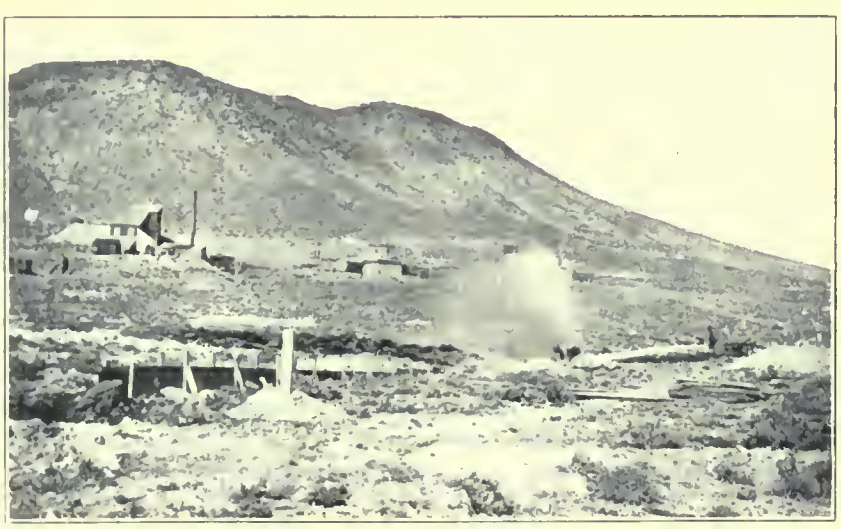
The camp of Round Mountain is situated on the east side of Big Smoky valley, two miles south of Jefferson canyon, and four miles from the site of the old camp of Jefferson, which was a prominent silver producer over thirty years ago.

The most convenient route to the camp is by automobile from Tonopah by way of Manhattan. The distance from Tonopah to Manhattan is 52 miles by the auto road, and from Manhattan to Round Mountain 29 miles. The machines usually follow the old stage-road to Austin, well toward the west side of the valley, crossing back to the east opposite the camp. The daily stage from Manhattan keeps near the foothills of the Toquima range and by this road the distance is only 18 miles. Freight is transported over the Nevada Central railroad to Austin, from which point there is a 52-mile haul over a good road. The site of the town, which has a population of about 500, is on a broad flat gravel slope, offering excellent drainage. Water for domestic purposes is hauled from Shoshone canyon, a mile north.

Town of Round Mountain, Nevada.

The mountain from which the camp receives its name is a low flat-topped rhyolite hill, rising less than 400 ft. above the surrounding country, and connected by a ridge toward the east with the Toquima range. On the west slope of Round Mountain is the Sunnyside group of the Round Mountain Mining Co., the most developed property in the camp. On the same slope, to the north, are the Great Western, now controlled by the Round Mountain Co., the Black Hawk, and the Sphinx. Along the connecting ridge are the Antelope, Daisy, and Fairview, all in rhyolite. On the northerly slope of this ridge, near the east line of the Fairview, is a contact with granite, and in the Fairview tunnel the granite has been encountered underlying the rhyolite, and dipping toward the valley.

Several dumps northwest from here, toward town, show granite, and the inference is that the ore-bearing area may not be found to extend farther in this direction. On the Daisy, in the hollow between the ridge and Round Mountain, and about 400 ft. west of the Fairview tunnel, is the 175-ft. shaft of the Crescent lease, the dump of which shows, besides the surface rhyolite, much fine slate. Here the rhyolite contains inclusions of both granite and slate. A few hundred feet farther west a shaft sunk by the Daisy company is said to have encountered quartzite at a depth of 170 ft., and after passing through 35 ft. of this entered calcareous slate. The rhyolite in the Black Hawk tunnel is quite dark, showing hornblende and biotite, with both feldspar and quartz phenocrysts. More commonly it is light and much kaolinized. W. H. Emmons and G. H. Garrey,* consider the rhyolite at Manhattan as belonging to the Tertiary. Presumably this is of the same period. The granite contains, in addition to the quartz and feldspar, widely varying amounts of muscovite, and shows a gneissoid structure. The shearing indicated by the structure of the granite is confirmed by the appearance of the rhyolite, the specimens of which indicate stress, alteration, and leaching.



Sunnyside Mine and Mill. Starting New Pit with Giant of the Round Mountain Hydraulic Co. in Foreground.

The veins are of two classes. The larger appear to occupy zones of shearing, if not of actual faulting, and the ore is rhyolite, more or less silicified and altered, often showing much iron oxide. These veins are comparatively flat, though varying much in both

* 'Notes on the Manhattan District,' Bull. U. S. G. S. No. 303

strike and dip. The main Sunnyside vein has a general northwesterly strike, but at one point makes a turn almost at right angles. The dip near the surface is northeast at an angle of 40°, but it flattens to 30° below. An interesting peculiarity is the frequent short drops in the hanging wall, as much as 18 inches, suggestive of step-faulting. In the upper levels the foot-wall is not well marked, and panning is the only method of determining what shall, or shall not, go to the mill. In fact, excepting in the case of the high-grade ore, there is little in the appearance of the ore to indicate its value. A piece of white rhyolite, apparently unchanged except for kaolinization, may run $2 or $200. The veins of the second type appear to occupy narrow fissures in the rhyolite; these are nearly vertical, but have a direction similar to that of the flatter veins. These seams, from a knife-blade to an inch thick, and of limited extent, are often very rich. They sometimes carry half an inch of almost solid gold, and appear to be the source of the gold that has made the dry-washing of the surface-gravels profitable. Rich pockets frequently occur where these vertical seams intersect the main vein. The gold occurs in finely divided particles disseminated through the ore, or in flakes, plates, and wires made up of connected fine crystals. Some specimens look like crushed masses of golden moss.

The main shaft on the Sunnyside has reached a depth of 550 ft. on the incline, and the vein, which near the surface was about three feet wide, is 22 ft. wide on the 450-ft. level. At the time of my visit, in April, the vein had been cut on the 550-ft. level, but the width had not been determined. The length of the pay-shoot had been proved for 400 ft. Another shaft, about 1000 ft. east, is also in ore, but whether it is on the same vein has not been determined. The Sphinx has a shaft 200 ft. deep and some drifts, but the mine was closed at the time of my visit, though it was to be re-opened in May. The Fairview has a long tunnel and considerable stoping ground, from which 20 tons is hauled daily to the mill on Shoshone creek. The Daisy and Antelope are principally developed by lessees. The Mulholland lease is said, by the secretary of the company, to have yielded $60,000 in a few months after the discovery of the camp. Much of this was very high-grade ore from which the gold was pounded out in mortars on the ground. Interesting stories are told of the shipments by suitcase, "which it took two men to lift into the buggy." There are six lessees on the Antelope. From one of them 12 tons shipped netted $700 per ton, in addition to which about 200 tons treated at the local mill yielded $32 per ton. The vein along the ridge where these claims lie has a northeasterly strike, and dips southeast near the surface. I was told that in the Antelope it straightens up and with depth dips northwest at an angle of 37°. This vein is from two inches to four feet in width. There is no work below the 100-ft. level on this property.

The manner in which the vein on the Antelope was discovered is interesting. The property was acquired soon after the discovery of the Sunnyside vein by C. C. Boak and others. A California pocket-hunter was hired to "post-hole the ground" and try to find a vein. In the course of his work the Californian panned the dirt at the mouth of a badger's hole, with such astonishing results that he jumped on his horse, rode to Manhattan, and telephoned Mr. Boak at Tonopah. The owners immediately secured an automobile and were soon on the ground, opening up the badger's hole. At the bottom they found his nest of sticks and straw on top of rock on which was a solid gold plate covering half a square foot. This specimen is still preserved at the company's office.

For the mill-man Round Mountain is a Paradise, in striking contrast with some of the near-by camps. Thus far the ore contains no sulphides. It is soft, and even with coarse crushing over 90% of the gold is saved on plates. There are now four mills operating in the camp. Those of the Round Mountain Mining Co. and the Fairview Co. have been in operation a year. The former is the largest and handles about 80 tons per day. It was erected at the mine, water being obtained from the Hydraulic Co. The ore, after passing a jaw-crusher, goes over a grizzly, whence the coarse goes to a bin, from which Challenge feeders deliver it to two Nissen stamps. The fine is similarly delivered to two 5-ft. Huntington mills. The former have a 16-mesh Tyler rolled slot screen, while the latter have a screen of the same type but about 25 mesh. The stamps are crushing about 10 tons each, and the Huntingtons 30 tons each, per 24 hours. Each of these machines is followed by amalgamating plates 10 ft. long, with a drop in the middle, but in the case of the stamps wooden riffles have been placed over the lower half of the plates. The tailing from the plates passes through a 9-ft. tube-mill and thence over two more amalgamating plates 5 by 8 ft., in parallel. I doubt if the final product would be finer than that which is ordinarily delivered through a 30-mesh screen. In nearly all cases the plates are given a fall of quite two inches per foot.

The Fairview mill is on Shoshone creek, one mile north, and consists of a grizzly, crusher, elevator to bin, feeder, and 6-ft. Huntington mill, with plates. The screen here is finer, both 30 and 40 mesh being tried, and the capacity is only 20 tons per day. All crushing is done on one shift.

The other two mills are but recently installed. The one at the Sphinx is a Huntington, and is being started on ore from the dump. The other, a 6-ft. Elspass mill, is a custom-mill, on Shoshone creek, now treating ore from the Matley & Morley lease, on the Great Western. While the district produces some high-grade ore, the bulk of the ore milled yields between $10 and $20 per ton, and in some cases less.

Power for mining and milling purposes is obtained on some mines from fuel oil, costing about 52c. per gal., and on others from burning wood, costing from $8 to $10 per cord. It is noticeable that the Sphinx, which has a gasoline hoist, put a wood-burning boiler in its mill. In Jefferson canyon there is a good stream of water, said to flow all the year around. All the water rights below the old Jefferson mill-sites have been purchased by the Daisy Mining Co.

and leased to the Round Mountain Hydraulic Co. By purchasing the old mill-sites, very nearly 1000 ft. fall for this water could be had and considerable power obtained at Round Mountain, but at present the water is more valuable for placer-working.

Large areas of the surface are covered to a depth of from 2 to 10 ft. with gravel enriched with gold by the erosion from the numerous small seams. At the time of my first visit, in 1906, Thomas Wilson had a lease on a portion of the Sunnyside, from which, with two dry-washing machines, he took out $30,000 in 70 days. This ground averaged over $5 per yard. Later, sufficient water was obtained for a sluice-head, and last year a considerable area was sluiced. Encouraged by the results obtained, the Round Mountain Hydraulic Co. was formed, the water rights owned by the Daisy Mining Co. were leased, and a 16-in. pipe-line laid down to bring water from Jefferson canyon. To this is being added the water from Shoshone creek, and it is expected to operate three giants. A large portion of the surface area of this camp is now under lease to the Hydraulic Company.

Concrete should not be mixed so wet as to wash the cement-mortar off the stone or aggregate used. Ram all concrete; its strength sometimes is increased 50% by thorough ramming. Do not attempt to ram concrete under water; the cement, if you do so, will be washed off the sand and stone forming it. In hot weather care must be taken to prevent concrete from drying too rapidly. Protect it from the sun, and keep it thoroughly wet. Portland cement needs plenty of water to ensure its proper and thorough setting. Sand for concrete should be reasonably coarse and clean. Fine sand, unmixed with coarse, should not be used. The coarser sand presents few surfaces, and is therefore better coated than the fine, and hence makes a stronger cement. On all masonry and concrete use the exact proportions which have been settled on. The coefficient of expansion of concrete and of steel is so nearly alike that there is no splitting apart of the two when the steel is embedded in cement. When cement is being used in large quantity, a sample amounting to 10 lb. should be taken from each car-load, a portion being removed from every fifth barrel, sealed, and labeled with the date and number of the car. These samples are to be kept in a dry place until that particular car-load has been used, and the concrete made from it has been placed and thoroughly set.

Detection of arsine in the air, according to Hebert and Heim, may be made by taking advantage of the well-known reaction with $HgCl_2$, but when a paper wetted with a solution of this salt is exposed to AsH_3 various other gases which possibly might be present may give a yellow tint which simulates that produced by AsH_3. It has been noted that passing the air through a solution of Cu_2Cl_2 will remove those interfering substances, and that if the air so purified is then passed through a U tube containing a slip of paper moistened with $HgCl_2$, the paper will not show a yellow tint unless AsH_3 be present.

FIRE AT THE HOMESTAKE MINE.

The importance of fire protection in mines where timber is used is evident on reviewing the expense and danger resulting from the conflagration at the Homestake mine, as described at length in the *Engineering News*, from which in part the following is taken, supplemented by additional data from a contributor. The workings are enormous, the amount of ore removed already having been about 200,000,000 cu. ft., and the length of underground track exceeds 50 miles. The entire workings are connected by many openings, which increase the danger of a general conflagration. The fire started at about 4 P. M. on March 25, 1907, as a result of ordinary blasting in old timbered workings, and the usual routine precautions were taken, the working place being visited after shooting. An hour later the fire was discovered, and immediately every effort was made to put it out. The air-pipes throughout the mine were arranged so as to be available for water in case of fire, but in the drift in which the fire occurred the pipes had not been laid. Hose and pipes were laid as soon as possible, but every effort failed to put out the fire.

An attempt was made to close all openings into the cross-cut and the foot-wall drift. The roof and sides of the cross-cut were boarded up tight with 1-in. boards and battens. In closing a tunnel the usual method was to stand 3 by 4-in. uprights, with 1-in. boards nailed on both sides, the space between being filled with wet clay. A cheaper and quicker method used in some places was to nail the boards on one side only in the manner of lap-siding upside down, the ledge formed by the lap being daubed with clay to make the joint air-tight.

As the air in the shaft was charged with a considerable percentage of gas, an air-lock was built near the 500-ft. station, in which the men could stop for a few minutes on the way to and from the fire. This lock was made by closing a part of the drift with doors, the air inside being kept pure by the admission of compressed air. A man was stationed in this lock whose duty it was to issue a check to each man as he passed through the lock on the way to the fire, and to see that all checks were returned when the relay returned. In this way it was almost impossible for a man overcome by gas to be left behind without being missed in time to be safely rescued.

After the pipe-lines were finished an attempt was made to get at close quarters with the fire. The two men at the nozzle were provided with leather helmets, which were fed with compressed air from the air main through a small hose. These helmets were made by the company's harness-maker, and fitted up at the machine shop. With these the men succeeded in getting close to the fire, and were doing effective work when the cross-cut began to cave behind them and they were forced to retreat. Soon after this the cross-cut became completely filled, so that a part of the fire was entirely shut off from further access. The caving of this cross-cut was no doubt caused by the fire burning out some of the timbers of the stope below, so that the water caused the fill to settle. It

was accordingly decided to close all the openings around the fire and endeavor to smother the fire with steam, and water was also turned into the open-cut above the fire in the hope that some of it would reach the burning timbers. After 7½ days an opening was made and two drifts were started in the broken ground surrounding the fire-area. These were driven until they reached rock which was highly heated, large masses being actually red-hot. As tests of the air in various parts of the mine showed continual increase of carbonic acid, indicating that combustion was still going on, it was finally decided to flood the mine. All the stations were boarded up to keep out floating timber which would interfere with the skips in hoisting water. All the water available in the company's system was turned into the mine, through shafts or the open-cut, and the water of Whitewood creek was brought in by a specially constructed flume emptying into the Savage tunnel at the 300-ft. level. The time required to fill the mine to the 225-ft. level was nearly 40 days, and it is estimated the space filled was 80,000,000 cu. ft. The unwatering of the mine was effected by skips, air-lifts, and Cornish pumps, an average of 10,000,000 gal. per day being maintained. When the air-lifts were taken out of commission, the high-pressure line was lifting water 336 ft. with a submergence of 171 ft., and the low-pressure line was working against the same head with a submergence of 135 ft., the two together raising about 600 gal. per min. These pumps were made by lowering two 8-in. pipes from the 300 to the 800-ft. level in the pipe compartment, and a 2-in. air-pipe was put inside each 8-in. pipe, extending down about 240 ft. below the discharge. The 8-in. pipes had a conical end at the bottom, provided with 2-in. holes in the cone-surface, the combined area of holes being 2½ times the area of the pipe cross-sections. On the lower end of the 2-in. pipes were pieces of pipe about 8 in. long with numerous small holes in the circumference, pointing upward at 45°, the ends of the pipes being closed with a cap. The discharge ends of the water columns were provided with special curved elbows, having flanged openings through which the air-pipes entered. Two skips of 2000-gal. capacity each were used in bailing. The air-lifts and skips discharged at the 300-ft. level. At the beginning of September the water was down to the normal level, being about six months after the outbreak. The mine workings and machinery were found practically undamaged by the flooding, except for the deposition of a little mud, and no human life was lost.

A good system of water-pipes maintained throughout the mine is the best protection from fire, and in special cases, where peculiar danger of fire occurs, it is often advisable to arrange the workings in separate fire districts which can be shut off by the closing of a few openings and the fire thus isolated. The great expense and difficulty of subduing mine fires only emphasizes the necessity for precaution. It may be added that only the older workings of the Homestake mine contain large quantities of timber in square sets and bulkheads. The system of stoping at present employed almost entirely dispenses with timbering, except on sill-floors and in chutes.

CYANIDE CORRESPONDENCE.

[The following is a letter from G. L. Guthrie, at San Juancito, Honduras, to Charles Butters, at San Francisco, handed to us by the latter. It has been deemed best to publish it in its original form, on account of its interest to those engaged in cyanidation.—EDITOR.]

Today I have turned over the completed cyanide plant, with all its connections at the mill and elsewhere in perfect running order, to the company. I take great pleasure in informing you that my year's work and worry has resulted in a plant successful in every detail.

The average daily extraction has been 88.29% silver, 91.87% gold, 90.19% total extraction.

Heads have averaged	38.623	oz.	silver,	1.087	oz. gold.
Filter residues	4.522	"	"	0.0844	" "

The filter takes on a fine cake, holds it, cracks very little, does not peel, washes perfectly, and discharges the residues cleanly. It will handle (although only 58 leaves are used) up to 25 tons, although I only put on 12 to 15 tons. Even with 45 minutes of solution and 20 minutes of water washes, it only takes 2 hr. 20 min. total time of operation per charge.

You remember the filter was sent down with a very shallow bottom and end doors were arranged so that the residue could be sluiced out. It washes chiefly by gravity and the 6-in. pump only runs 24 minutes per charge.

Mr. Patterson was given to understand that they could not excavate lower down and he designed the filter accordingly. It did not appeal to me to have to lose so much time cleaning out residue, so I put in pointed discharges and arranged a system of water pipes, so that by opening one valve eight small streams of water dislodged the slime, the result being that the filter discharges cleaner and quicker than either the Devisadero or Copala filters.

The lower slide-bolts fastened to each end of each filter-mat makes it very simple to remove the mats for acid treatment, and the water-glasses in the suction-hose show just how each mat is working. The filter has run nearly three months and I have not had to repair a single mat. The discharge is clear, and I have never had enough trouble with receiving-vats, gold-vats, or sand-filter to make it worth mentioning.

The vats, pumps, valves, and friction-clutch lever are so arranged that a cheap native runs the filter per shift, hardly leaving the filter-platform. I honestly believe it is the simplest run filter installed up to date. Certainly, 90.19% extraction, as compared to 75% under the old system, shows up very well, especially considering the new plant has only been running 11 days. I have cut expenses all to pieces, and I feel sure that if the plant is run properly, the company will never regret the change. A competent force is broken in, the work and treatment systematized, and Mr. Schram, my successor, is a very capable man, so I consider that I have turned the plant over in first-class condition. It has taken a longer time than I expected, principally because the company delayed ordering the things that I deemed necessary, lumber was slow in coming in, and the con-

struction force at my disposal, especially mechanics, has never been adequate, except the masons.

The plant was built principally on a slime-dump in a gulch, and I have had to weave in the new plant with the old. The same at the mill, without shutting either down but a few days, and I have had to use a lot of the old material. The entire responsibility of laying out all constructional and mechanical work, besides the metallurgical end of it, has been up to me. This letter is not meant to throw bouquets at myself or tell 'a hard-luck story,' but just a statement of what the work has been.

I have made some mistakes but have rectified them in time. A masonry sump built on a slime-dump cracked and had to be repaired. I had trouble at first with the Gould pump and had to re-adjust some launders. The Meese & Gottfried engineers claimed that my power-transmission was weak at the agitator end, but this was not proved, for I ran the first five agitators over two months without even tightening the new rubber belt that drove them or having any mechanical parts run warm, but of course I am glad to have the heavier gears in. I have installed seven large and one small mechanical agitator and two hand-power stirrers of the slime-collecting vats; built a 200-ton and a 400-ton masonry vat; built new or re-built 13 wooden vats ranging from 18 to 26 ft. by 11 ft. deep; set up 14 pumps from 3 to 6 in. and one compressor; outfitted the zinc-room into quite a neat efficient extractor-house with its 11 wooden boxes of six compartments, each cock-compartment 18 by 18 by 22 in., 40-frame press, 5-hp. motor, pressure-pump, and 4 by 12 ft. precipitate-dryer.

Luckily the boxes were made, but not connected up. The carpentry and masonry work, on account of the rotten condition of the red plant, the new addition to the red zinc-room, and the soft condition of the ground, has been very great. I have had to use all the tact and diplomacy I could muster to keep peace with all the employees and get work turned out, and I believe every employee of the company feels friendly toward me.

The following is an outline of the ore and treatment as at present: The total product of the 45-stamp mill (850 lb. per stamp) is treated as slime, there being between 15 and 17% fine sand in the slime, which will not pass 200 mesh, and in fact the slime itself is practically all fine sand. The ore is very hard quartz. The sulphide and oxidized ore are mixed for crushing.

There is about 2½% of concentrate in the ore and a good deal of copper and iron, some lead, zinc, and antimony, and a lot of free coarse gold and silver. The ore is crushed through 30 mesh with 3 in. discharge, 99 drops per minute and a dilution of 6 to 1, crushing in solution. The pulp is pumped to classifiers, the slime overflowing to two 18 by 11 ft. slime-collecting vats with hand-power agitators in order to regulate the specific gravity of the slime drawn out for treatment. The overflow is clear and flows to a 16 by 11 ft. mill-solution vat and from there pumped back, a rise of 54 ft., to a 200-ton masonry mill-feed vat. The oversizes flow to the two 3½ by 16 ft. Smidth Pettle mills and there the discharge is re-classified.

The slime from the collectors flows by gravity to a centrifugal pump, which either pumps it to five old amalgamation pans or to three separator-pans for a preliminary treatment in order to get the proper dilution and to make up the proper strength of solution, or directly to an open launder connected to the same pans, where it flows 200 yards to two 26 by 11 ft. combination collection and treatment-vats, where regular treatment takes place with agitators and pumps, the solution being kept up to strength. Charges of 40 tons dry slime are drawn from these vats and transferred in rotation to the six regular 20 by 10 ft. treatment-vats, four of which have agitators and two conical bottoms for pump agitation. In rotation the charges are treated, settled, decanted, and transferred to the 22 by 11 ft. filter-feed vat and from there falls by gravity to the filter.

The solution from the filter passes to the two 20 by 10 ft. receiving-vats and on account of the site is pumped to a 20 by 10 ft. settling-vat and then by gravity to two 12 by 4 ft. sand-filters and from them to the zinc-boxes.

Treatment lasts about 90 hours, but the slime is actually in contact with the solution over 100 hours. The strength of the solution is kept up to about 0.6% KCy, 0.13% CaO, and 1.6 lb. lead acetate is added per ton of dry ore at beginning of actual treatment. Dilution during treatment is a little over 2 to 1. The zinc-box heads assay between $6 and $8; the tails a few cents. Lime is added principally in the ore-bin, and some in the pans at the preliminary treatment. On account of this being the dry season, we are short of power at the power-house, and consequently I can give very little aeration into the circulation pumps. Between 84 and 88 tons are treated per day. With another tube-mill the plant would easily handle 110 to 120 tons of slime, and with a small sand-plant it would take care of 150 tons.

As soon as things are better arranged and a better line gotten on the treatment, they should be able to cut down the strength of the cyanide alkali, and especially the lead acetate. I have made a good many experimental runs, which have been proved by actual results in treatment. On account of necessary repairs at the mill I was able to make the change over to cyaniding, only shutting down the mill for two days. During all construction the old plant was only shut down for what was equal to eight or nine days time and the new improvements put in from time to time more than increased the output to equal the time lost. They made me so mad a number of times that I felt like throwing things. They seemed to think I could put a pulley on a line-shaft without stopping it, and they seemed to think more about not shutting down the little old plant than they did about getting the new one built.

I forgot to state that a 75-hp. motor runs the plant proper, a 35-hp. motor the filter-apparatus, and a 5-hp. motor the zinc-room machinery. Water-power runs the mill.

MINING CONDITIONS ON THE RAND.

By Thomas H. Leggett.

*In a paper† presented to this Institute in August, 1900, I drew attention to the great cost of sinking the very deep vertical shafts that were then being seriously proposed as necessary for the development of the deeper areas, pointing out the strong advisability of working this ground by means of inclines from the existing shafts, then from 3000 to 4000 ft. vertical. In this paper it is stated that practice upon the Rand tended toward fewer vertical shafts and more underground inclines, especially for the very deep mining about to be undertaken at that time. But the 6000-ft. vertical shafts, at one time so much discussed, have never been started, nor are they likely to be.

The necessity of placing all deep shafts farther apart, in order to make them control and exhaust larger areas, was also dwelt upon. This economy was vitally necessary for both financial and technical reasons, few of the deep shafts being operated to anywhere near their full efficiency, and to further this object the advisability of consolidating many of the deep-level companies was pointed out.

The hard times that the Rand has been going through during the past few years have emphasized these points, with the result that the very deep vertical shafts are no longer suggested, while the amalgamation of a large number of the deep-level properties has already been consummated and other amalgamations are under way.

There were many deep-level companies formed 8 or 10 years ago with areas of from 200 to 300 claims (from 280 to 420 acres), which were to be developed by means of vertical shafts placed about 2000 ft. apart. Many of these properties have been consolidated, so that the areas are now multiplied two or three times, while the distance between shafts has been increased from 3000 to 4000 ft. In some instances, properties of large area are being opened up by a single deep shaft, which is permissible where connections can be made with adjoining properties, so as to give the two exits required by the Transvaal law.

Under these conditions, several years ago I started a single seven-compartment shaft to be sunk approximately 4000 ft. to develop a property of 254 claims (about 356 acres), each of the six hoisting compartments being 5 by 6 ft. inside of timbers, and the pump and ladder way 6 by 6.5 ft., and as stated, several similar single shafts have since been started. In short, economy in all directions is the order of the day, and necessarily so, since new capital is not easily found for defraying the cost of expensive deep-level development.

Consolidation of Properties.—An excellent instance of the merging of deep-level properties is the consolidation of the Knights Central with the South Knights. The Knights Central has an area of 444 claims (622 acres), a capital of £525,000, and is developed by means of two 5-compartment shafts, about 2000 ft. apart, and each about 2200 ft. deep. This company today has 282,000 tons of ore developed, assaying about 8 dwt. over an average width of 4 ft., which is highly payable ore, but it has only about £50,000 cash in hand, or not nearly enough to build the necessary 200-stamp mill and cyanide plant and to develop the mine adequately. The South Knights property has an area of about 450 claims on the dip of the Knights Central reef or adjoining that property on the south, where its shallowest depth of reef is about 5000 ft., and it has a paid up working capital of about £300,000 cash in hand. This amount of money is quite inadequate for the necessary shaft sinking, equipment, and development, to say nothing of the necessary milling plant. At the present unfavorable period it would be impossible to raise additional capital, as is evidenced by the fact that not a sod has been turned upon the property, although the company has had nearly $1,500,000 cash in hand since its formation several years ago.

The consolidation of these two properties gives an area of 894 claims (1250 acres), insures a long life to the enterprise, and furnishes the necessary funds for bringing the property to a producing stage, since the cash in hand will then amount to £350,000. It also puts the shareholders of the deeper property within measurable distance (probably 12 or 15 months) of receiving a return upon an investment which has already lain fallow for five years, and which, could they succeed in raising the additional capital necessary to bring it to fruition, would still require six or seven years more.

This example is a fair type of the consolidations recently accomplished and still going on, chiefly between the mines forming the second row of deep-levels (average depth of reef about 2600 ft.) and the deeper ground beyond, although in some few instances amalgamations of deep ground with the nearest outcrop companies are also being discussed. These combinations are in almost all cases advisable, from both technical and financial standpoints. The technical reasons were always fairly apparent, the financial are now evident.

Financial Conditions.—It is pertinent to touch upon the financial aspects of these consolidations, not only because the mining business, like all others, is governed by them, but also because one of the leading mining journals of the United States has published the statement that the mines of the Witwatersrand were greatly over-capitalized. I believe it is demonstrable that the majority of these companies are not over-capitalized.

In the consolidation of the two properties above mentioned, the Knights Central issued £375,000 fully paid £1 shares in payment to the South Knights for its entirely undeveloped property and its £300,000 in cash. The South Knights has a capital of £650,000 (in £1 shares), of which but £500,000 are issued, including 150,000 shares working capital guaranteed at 35s., this latter feature being the cause of the present large amount of cash in hand. It is evident that the deeper property suffers a large shrinkage of valuation by this consolidation; it is almost invariably the case that the company owning the deeper

* Abstract from Bi-monthly Bulletin of the American Institute of Mining Engineers, May 1908.
† *Transactions*, A. I. M. E., Vol. XXX, pp. 947 to 987.

and generally largely undeveloped property has thus to suffer in these amalgamations.

With respect to this very deep ground, the engineer earliest on the Rand, Hennen Jennings, was always very cautious, while John Hays Hammond uttered a note of warning in 1901, with which all conservative engineers on the Rand agreed, when he said:* "The results of the developments in the deep-level areas have been so satisfactory as to engender a certain recklessness on the part of mining companies owning very deep reefs. The exploitation of certain of these areas is not regarded by conservative engineers as at present justified, in view of the large intervening tracts of undetermined value which separate mines in operation from the site of proposed mining upon these very deep-level areas."

The redeeming feature of the formation of companies on these deeper areas was the invariable provision of a good round sum for working capital, as in the case of the South Knights, and such was the faith of the issuing house in the value of these properties that this working capital was guaranteed at prices usually much above par. The result has been, however, that by far the major part of this working capital has had to be paid by the guarantors (not a pleasant position when the same shares can be bought today for one-fourth to one-sixth of the guaranteed price), and this liability can never be avoided, not even by the liquidation of the company.

It speaks well for the character of Rand finance that none of these deep-levels was floated without this provision of immediate working capital and in large sums. The consequence is that the deeper companies are in the position to make much better terms when combining with their northern neighbors than otherwise would be the case, while to this consolidation many of them must inevitably come, for the reasons already given.

With reference to the alleged over-capitalization of the Witwatersrand companies, a record of the dividends paid by 47 of them (all the data now available) for the year 1907 shows an average of 44% on the aggregate capital, while certain properties did much better, as, for instance, the Crown Reef, 210, and the Ferriera, 300%. The Rand Mines, comprising a group of nine producing deep-level mines, paid 130% in dividends during 1907, and promises to increase this rate during 1908. According to Ross E. Browne, the total expenditure in shafts, development, plant, and equipment by these nine companies before reaching the producing stage averaged £620,000 per company; consequently a large capitalization is warranted. The report of the Mines Department of the Transvaal for November, 1907, shows 71 mines with mills in operation on the Rand; hence it is evident from the foregoing that the majority of these mining companies are far from being over-capitalized. It is undoubtedly true that the stock market has over-capitalized these companies several times, and probably this fact has led to a confusion of ideas on this subject. Doubtless some of the deep-level mines, more especially the developing ones, today seem to be over-capitalized, but they did not so appear at the time of their flotation, else the working capital would never have been so cheerfully guaranteed at a high premium. Moreover, it is far from certain that they will be so regarded a few years from now, when further development and improved economic conditions bring their welcome changes.

A Typical Scene on the Rand.

About five years ago I examined a developing deep-level mine that showed only 40% of 500,000 tons of ore in reserve to be payable. Today this property is

*"Gold Mining in the Transvaal, South Africa," *Trans.* A. I. M. E., Vol. XXXI, p. 852.

making profits of £60,000 per annum and steadily improving, while it is unquestionably crushing much of the ore that five years ago was unpayable.

Working Costs.—As a mining district grows older the working costs almost invariably decrease, provided the district maintains a healthful activity with advancing years, and this has been the case on the Witwatersrand, the result being as follows:

1898, average working costs of 65 companies..25s. 1.3d.
1899, average working costs of 42[1] companies..25s. 2.7d.
1906, average working costs of 58 companies..22s. 1.0d.
1907, average working costs of 56[2] companies..20s. 8.0d.

[1]The Boer war broke out in October, hence the records are incomplete.

[2]Two less than in 1906, due to exhaustion of the Bonanza mine and incomplete records from one other mine.

These costs include mining, development, crushing, sorting, milling, cyaniding, maintenance, and general expenses, but they do not cover depreciation and amortization, these items being more properly apportioned by the directors at the end of the year. These results show the important decrease of 4s. 6d. per ton since 1899, and are therefore approaching now to the 6s. reduction predicted by Mr. Hammond in 1901, but it has taken time to attain this result, as I then pointed out it would do. A comparison of the costs in 1907 with those of 1906 shows a decrease of 1s. 5d., or 34 cents, per ton, due chiefly to decreased wages and increased efficiency of both white and colored labor, including the Chinese in the latter category, though increased crushing capacity through the use of heavier stamps (up to 1670 lb. per stamp) and re-grinding in tube-mills have also aided.

In 1906, 58 companies mined and milled 13,065,624 tons of ore, at a total cost of £14,411,219, while in 1907, 56 companies mined and milled 14,861,234 tons, at a total cost of £15,351,749, being an increase of 1,795,610 tons for an increased cost of only £940,530. Most of these economies were attained during the latter half of 1907, after the strike of white miners, and some mines made startling reductions, as, for instance, the Robinson, which reported costs of 14s. 9d. for November, and the Glencairn, of 15s. 1d. per ton.

Such strenuous and successful efforts are now being made to reduce still more the working costs on the Rand that I think it safe to anticipate another large decrease for the year 1908.

Output and Dividends.—The total output of the Witwatersrand district for 1907 was 6,220,227 oz. (213.27 tons) of fine gold, equal to an average of 17.75 tons of gold per month. The present yield exceeds 19 tons of gold per month. The value of the output is approximately £26,436,000 ($128,572,000), an average of $10,714,300 per month for the year. This amount does not include the 'outside' districts of the Transvaal, which are producing in addition about 20,000 oz. per month.

The returns available to date from 56 companies show a total yield during 1907 of £25,154,591, which is equal to 33s. 10.2d. per ton, and a total profit of £9,805,906, equal to 13s. 2.3d. per ton. The yield per ton for the entire district is practically 34s., or $8.25, which is about 6s., or about $1.50, less than the average return of 10 years ago. On the other hand, working costs have been reduced 4s. 6d., and are still decreasing, while nearly three times the amount of ore is being crushed as in 1897, although the number of producing companies has not been increased 25 per cent. The number of stamps, however, has been more than doubled. 3567 stamps in 1897 and 8375 stamps in November, 1907. Small companies have dropped out and larger ones, both outcrop and deep-level, have taken their places, while many outcrop companies have greatly increased their crushing capacity.

The dividends for 1907, declared up to January 1, 1908, amount to £6,937,187, or £1,202,026 in excess of the dividends for 1906, and these amounts are exclusive of the 10% profit tax, from which the Transvaal Government should derive an income for 1907 of about £760,000. These dividends represent slightly more than 25% of the gross output of gold from this district for the past year, certainly an excellent record for any mining district.

In the paper entitled 'An Estimate of the Gold Production and Life of the Main Reef Series, Witwatersrand, Down to 6000 Feet,'‡ Frederick H. Hatch and I predicted an ultimate annual yield of £30,000,000. The yield is now within 12% of that estimate, which it bids fair soon to reach. The output for the entire Transvaal for 1907 was £27,403,738, an increase of £2,823,741 as compared with 1906; practically all this increase was due to the Rand proper.

Labor.—There is one important point that does not seem to be generally understood, namely, the introduction of the Chinese into the Transvaal is not on a par with their introduction into Canada, Australia, the United States, or any of the countries that object to their presence. In these countries the Chinaman comes immediately into competition with white labor, while in the Transvaal he does not, because there already exist there two planes of labor, the white and the black, and the Chinaman has been rigorously confined to the latter.

In any country where white and black labor work side by side, there are always certain things the white laborer considers *infra dig.*, and he will always relegate these to the black. The white man is always scrupulously careful to keep the black on the lower level, and to not allow him to rise, since that would mean competition. In the Transvaal the white miner has the overseer's position and the black man does most of the hard work. Engine-drivers and mechanics are white men; in fact, skilled work of all kinds has always been done by the white man, and always will be done by him. The Chinese have simply supplemented the supply of Kaffirs, and have never been in competition with the white labor any more than are the 100,000 or more Kaffirs now at work in the mines in such competition. Nobody has ever objected to these Kaffirs working with, and under the direction of, the white miners, and as there are 6,000,000 of them south of the Zambesi alone, the country can never be made a 'white man's country' in the full sense of that term.

It is evident that the feeling against the Chinese, founded as it is upon a valid and practical cause in

‡ *Transactions* Institution Mining & Metallurgy, Vol. XII, p. 44.

other countries, has no such basis in the Transvaal, and is there but an empty sentiment; one, however, that was worked to such an extent in England, where the average man knew nothing of the real conditions and supposed the Chinese would eventually oust the Briton, that the former have to be sent home on the expiration of their contracts. This has been going on for some time, so that out of the 53,000 Chinese in the country at the end of 1906, it is estimated that but comparatively few will remain by the end of this year.

The repatriation of the Chinese is a loss to the mining industry of the Rand, since they are more intelligent than the Kaffirs and have become adept at mining work. Moreover, they are on a three-year contract, while the Kaffirs seldom stay for more than six months at a time, though they often return.

The question now is, can all the Chinese be promptly replaced by Kaffirs, to whose scarcity after the war the introduction of the coolie was due? On this point divers opinions have been expressed, but thus far they have been replaced, in the month of November, 1907, no less than 4610 Chinese having been sent away and their places filled by Kaffirs. The Transvaal Government, acknowledging its responsibility for sending away the Chinese, has put itself on record as desirous of aiding the mining industry in every way in its power to secure Kaffirs, and as they have perhaps more ways of doing this, it seems highly probable they will succeed.

As to white labor, the miners' wages, heretofore excessive, have been reduced, partly due to the necessity of giving work to the hundreds of unemployed in and around Johannesburg, with a resultant benefit to all concerned, since the efficiency of this class of labor has been much improved. Before the strike the white miners' pay was £1 per fathom stoped, based on the work of the poorest miner, with the result that capable contractors made enormous profits; today contract prices are reduced, and, what is still more essential, are based upon the capacity of the best miners.

Annual and Quarterly Reports.—The mining companies on the Witwatersrand publish such full and complete reports of their operations that they can well serve as a model in this respect to the rest of the world. They comprise reports of the board of directors, the consulting engineer, and the manager, and give very full and complete tables, showing the technical details, costs, and results of the operations, together with full financial particulars, comprising usually a balance sheet, revenue and expenditure, or profit and loss account, and an appropriation account; but above all they show the tonnage available at the end of the year, and its value, and describe the mine development and the appearance of the bottom levels of the mine.

The quarterly reports issued regularly to the shareholders give the results of the preceding three months' work, yield, costs, and profit, together with a short description of the appearance of the mine, latest developments, tonnage of ore blocked out, and often its assay-value. Many mining companies in London now send monthly postal cards to each stockholder giving the amount of ore treated, the yield, cost, and profit for the preceding month, and any important feature of the month's development.

In this day of reform in corporate management it is to be hoped that many of the American mines, well managed in all other respects, will copy the methods and practice of the English companies.

Outlook.—With regard to the outlook for the mining industry, it is several years since I was in Johannesburg, and it is therefore appropriate to quote the views of those who have more recently visited these goldfields.

W. Fischer Wilkinson says:* "There is still a considerable margin between the average working costs and the average recovery [average recovery $8.25, average costs $5 per ton.—T. H. L.], and a still further lowering of the grade may be expected, carrying with it a corresponding increase in the tonnage available for profitable mining. Low-grade ores of a value of 5 dwt. per ton or so, which were formerly considered worthless or of little value, are now becoming a valuable asset, and the prospective lives of the working mines are constantly having to be re-estimated to meet the altered conditions. Undeveloped properties or those partially developed, whose prospects with costs at 30s. per ton or thereabouts were not bright, can look forward to a profitable existence now that costs have been in many cases reduced to 20s. or less. The possibility of working low-grade ores profitably has now been amply demonstrated, and there is no danger of the Transvaal's failing to contribute heavily to the world's supply of gold for many years after the exhaustion of the richer mines of the Central Rand."

Evidence given before the Mining Commission in Johannesburg during 1907 was to the effect that 39 of the dividend-paying companies had an average life of 12 years and 8 months. Since the life of every mine exhausted to date has been greatly under-estimated, sometimes by as much as 50%, and since much lower grade ore will eventually be worked than is at present milled, it is safe to say that the average life of the above 39 properties will be at least 15 to 16 years. It would be interesting to have the estimated average life of a greater number of the properties; but as there were 71 mines that dropped stamps in November, 1907, of which about 50 are paying dividends, and as more deep-level mines will soon join the ranks of the producers, it seems reasonable to expect not only a maintenance of the present output for some years, but even an increase up to £30,000,000 per annum for a part of that time.

As regards development in the deep-level mines, upon which so much depends, although high-grade ore, assaying in the ounces, was struck in the Cinderella Deep at a vertical depth of 4000 ft., and while the Knights Central (still developing) has large quantities of 8-dwt. ore at a vertical depth of about 2400 ft., I am informed that other mines show long stretches of 5 and 4 dwt. ore, with only occasional high-grade stuff. It is therefore imperative that costs should be reduced still further, in the near future, before these deep-level mines reach the pro-

* *Engineering & Mining Journal*, Vol. LXXXV, p. 53.

ducing stage; and in this connection it is interesting to note that Mr. Browne, who has recently made a two-year study of the conditions on the Rand, states that if the white and the Kaffir labor were made more efficient, which he believes can be done, and the cost of supplies lessened, costs could then be reduced to 15s. per ton. This is a most encouraging statement, coming as it does from a specialist in the subject, and made at a time when the working costs were 22s. per ton.

There is no doubt that costs will be reduced below 20s. during the present year, probably to 19s., perhaps even better than this, for higher efficiency of both white and black labor is now the earnest objective of all the mine managements, and when one reflects that these two items comprise about 62% of the total costs it is evident what an effect the greater efficiency of labor will have. It is also to be noted that as the efficiency of the miner increases the cost of supplies decreases; he consumes less or makes a given quantity go further.

Improvements in the metallurgical practice have brought the extraction up until it is now about 95% of the assay value of the ore, an important matter when one considers that the saving of one grain of gold per ton of ore crushed means, at the present scale of operations on the Rand, an increased yield of $600,000 per annum. Finally, Mr. Wilkinson considers 5-dwt. ore to be now a valuable asset in any Rand mine—all of which goes to show how time is working in favor of all the mines on the Rand, and especially the deep levels.

In more than one deep-level mine the stopes have turned out better than the assay-plans have indicated, and when one reflects that the drifts are now from 200 to 300 ft. apart (even 400 ft. in some deep-level mines), and the connecting winzes separated by distances of 400 ft. or more, it is evident how this may happen. Again, later development has shown that poor zones occur in more or less horizontal stretches, so that the bottom levels of a mine may all be in poor ore at the same time, but on pushing down through this zone the development has again disclosed the normal grade of reef.

Hence it is now thoroughly well recognized on the Rand that deep-level mines must have from 5 to 10 miles of intelligently directed development work on the reefs themselves before a valid opinion can be formed of the value of a mine.

To summarize, we find that the Witwatersrand output has increased about £2,800,000 in 1907 as compared with 1906, while the dividends have increased £1,200,000, and working costs have decreased 1s. 5d. for the same period, with another heavy reduction practically assured during the present year. The use of tube-mills and of heavier stamps has increased the stamp-duty about one ton, until it is now 5.8 tons per stamp, while the extraction has been increased to about 95%; hence tailing that a few years ago ran about 1 dwt. or $1 per ton now assay but half that amount, with the result that lower grade ore can now be worked than ever before; in fact, one mine is actually in operation at present on a yield of only $4.31 per ton, or say 4.5-dwt. ore.

The possibility of a shortage of Kaffir labor by next July or August is to be considered, but this may easily prove to be not as serious as some now consider it. The Rand has been going through very depressing times, the natural reaction from over-speculation, with the result that everything is viewed there today "as through a glass, darkly." But the hard times have had a salutary effect; efforts are being concentrated along the proper lines to secure economy in all branches of its great gold-mining industry, and the results of these are bound to tell favorably in the near future.

The quality of water in the Great Lakes has been an object of investigation by the U. S. Geological Survey for the past year, comprising analyses of samples of water collected from various inflowing streams and also of the outflow from each of the lakes. These analyses show that except along shore at times of high wind the water in all the lakes is practically free from suspended matter of any kind. The water of Lake Superior contains the least amount of dissolved solids; that of the Lake Huron outlet, including water derived from Lakes Superior, Michigan, and Huron, ranks next. Lake Michigan is third, with about twice as much dissolved matter as Lake Superior. The outlets of Lakes Erie and Ontario are almost identical in quality. Lake Ontario is a trifle more highly mineralized than Lake Erie and contains two and a quarter times as much dissolved matter as Lake Superior water. The notable changes in composition passing eastward from Lakes Superior and Michigan are a gradual decrease in silica and carbonic acid and a gradual increase in chlorine and the sulphate radicle; calcium and magnesium increase and then decrease, while the alkalies decrease and then increase. Calcium, magnesium, and the carbonate radicle amount to about 80% of the dissolved matter. It is found that 3,350,000 lb. of dissolved mineral matter passes out of Lake Ontario each year. Of this quantity, 441,000 lb. comes from Lake Superior, 666,000 lb. from Lake Michigan, 913,000 lb. from Lake Huron, 840,000 lb. from Lake Erie, and 490,000 lb. from Lake Ontario.

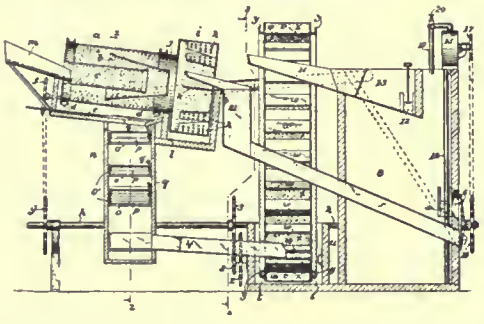
The old Port Royal mine of the Pittsburg Coal Co. is to be emptied of the water that has filled it for years. Three ten-inch holes are being drilled from the surface to the interior of the mine, a distance of 365 feet, and in each will be placed a six-inch pipe. Each of these pipes will be capable of discharging 2,000,000 gal. of water per day by the air-lift process, all of which will be emptied into the Youghiogheny river. When the drill penetrated the old workings the pressure of the gas threw the water as high as the derrick.

Chlorine is found in only three minerals in the igneous rocks, namely, apatite, sodalite, and the marialite molecule of the complex silicate known as scapolite or wernerite. The chief original chlorine-carrier is sodalite, containing 7.3%. The total chlorine in the original rocks is estimated as 0.01 per cent.

MINING AND METALLURGICAL PATENTS.

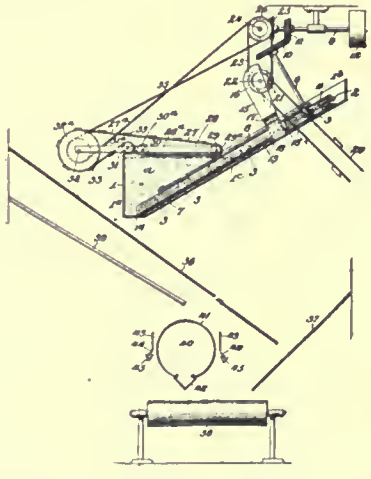
Specially Reported for the MINING AND SCIENTIFIC PRESS.

ORE-WASHING MACHINE.—No. 887,490. Hugo H. Meyer, Racine, Wisconsin.



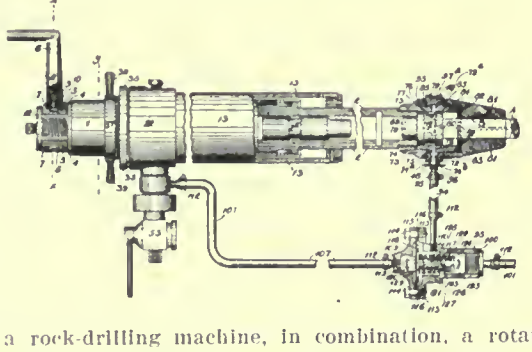
In an ore-washing machine the combination of a riffle-box containing a series of reversely inclined riffle-plates arranged one above another, a trough having a discharge opening at the bottom over the upper riffle-plate, a rotary screen mounted in said trough, an elevator wheel having a series of buckets around its rim, a trough containing the lower part of the elevator wheel, a conduit leading from the lower part of the riffle-box into the lower part of said wheel, a settling-tank, a chute extending from the upper interior part of said wheel to said tank, and a return conduit leading from the upper part of said tank into the screen trough, substantially as described.

AMALGAMATING APPARATUS.—No. 887,319. Fred D. Fenn, Boise, Idaho.



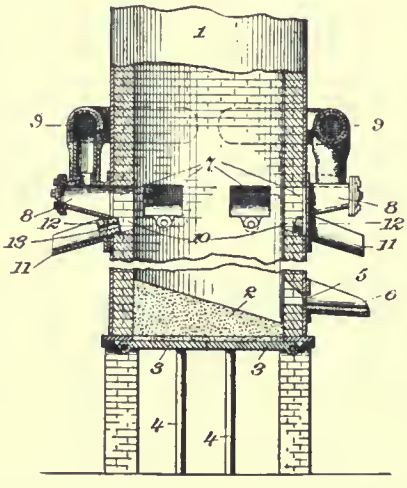
An amalgamating apparatus including a mercury tank, a chute having its lower end located therein, an endless conveyor located wholly within the tank and passed through the lower end of the chute, and a feed spout passed transversely through the chute and inclosing one run only of the conveyor, said spout opening into the chute and being extended to the bottom of the mercury contained in the tank.

ROCK-DRILLING MACHINE.—No. 887,801. Henry Hellman and Lewis C. Bayles, Johannesburg, Transvaal.



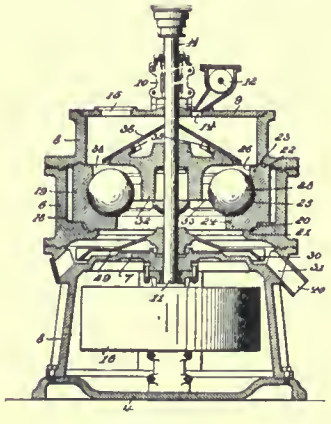
In a rock-drilling machine, in combination, a rotatable power-cylinder, means for rotating said cylinder, a reciprocal percussive member in the power-cylinder, a front head screwed to the cylinder, a swivel piece surrounding the front head, means for conducting water to said swivel, the front head having a passage placing the swivel in communication with a longitudinal hole in the bit, a nose-piece screwed to the front head and serving as a retaining device for the swivel, and a bit supported by and non-rotatable in the nose-piece.

METALLURGICAL FURNACE.—No. 887,777. William S. Dempsey, New York, New York.



In a furnace, the combination of a melting chamber having a series of openings formed in the walls thereof, a twyer box at each opening, each of said twyer boxes being provided with an air-valve and a slagging spout, and a removable plug partly closing the outlet through the slagging spout.

PULVERIZING OR GRINDING MILL.—No. 888,077. James W. Fuller, Jr., Catasauqua, Pennsylvania.



A pulverizing or grinding mill provided with a spider-frame having two series of supporting arms, a conical material distributing device supported by one series of said arms, pushers carried by the other series of said arms, a grinding ring supporting balls between said pushers, a sweeper, a shaft carrying said sweeper and spider-frame and actuating the same and means for removably connecting said conical device with said supporting arms, substantially as and for the purposes described.

PROCESS OF MAKING BARIUM OXIDE.—No. 886,607. Charles B. Jacobs, Port Chester, New York.

The process of reducing barium carbonate to barium oxide, which consists in suspending the carbonate in a finely divided condition in and throughout a uniformly porous reducing agent, and subjecting the same to heat to liberate the carbon dioxide, whereby the carbon dioxide is reduced to carbon monoxide and ready exit provided for the escape of the gas. The process of converting barium carbonate into barium oxide, which consists in suspending the carbonate in the form of fine particles throughout a uniformly porous mass of carbon, subjecting said mass to heat to decompose the barium carbonate.

MINE REPORTS.

DURBAN ROODEPOORT DEEP, LTD., TRANSVAAL.

The Durban Roodepoort Deep is the smallest producer among the subsidiary companies of the Rand Mines, Ltd., showing a net profit for 1907 of £41,073. The outlook for future operations has so improved through the opening up of the 'reef series' in the new shaft at a depth of 1460 ft., that the company's mill will be increased from 60 to 100 stamps, with the corresponding accessory equipment. The ore-reserves are given as 252,051 tons on the Main Reef, assaying 6.5 dwt., and 385,649 tons on the South Reef, assaying 7.8 dwt., making a total of 637,700 tons averaging 7.3 dwt. gold per ton. Development aggregating 11,416 ft. was done during the year, adding 395,458 tons to the reserves, the development cost per ton being 33.7c. Ore mined was 177,565 tons, waste sorted out 40,385 tons, net tonnage milled 137,180, having an average value per ton of 7.866 dwt. The 60 stamps dropped 330 days, giving a duty of 6.926 tons per diem. The recovery was 5.644 dwt. per ton, or 97.65%. Mill recovery was 71.75%, the cyanide operations adding 25.9%, of which 18.03% was extracted from sand and 5.61% from slime. Mining costs were $3.42, milling (including sorting and tramming) 85.3c., cyaniding 34.03c., tailing disposal 12.6c., making a total of $4.78. Total expenses, including development and administration, amounted to $6.82 per ton, against a revenue of $7.72, leaving a working profit of 90c. per ton.

CROWN DEEP, LTD., TRANSVAAL.

The Crown Deep, Ltd., is the best revenue-producer of the group of properties included in the consolidation known as the Rand Mines, Ltd. The net profits for the year 1907 amounted to £394,695. Dividends from the company's interest in the Robinson Central Deep, Ltd., added £59,189 to income, and from other sources, including balance brought forward, the available net sum of £547,281 is reached. The ore reserves are estimated at 1,323,253 tons, of which 703,788 tons are on the Main Reef and Main Reef Leader, and 619,465 on the South Reef. The development work for the year represented a footage advance of 11,030 ft., yielding additional proved ore-reserves of 552,236 tons, having an average assay value of 8.8 dwt. per ton. As the mill-capacity is practically 400,000 tons per annum it will be seen that the Crown Deep has a reserve supply blocked out three years ahead. Total mine costs amounted to the equivalent of $2.97 per ton, distributed as follows: developing 37.7c., stoping $1.413, shoveling and tramming 61.5c., hoisting 22.3c., pumping 10c., surface haulage 6c., general 20.2c. The development cost per ton of ore exposed by driving was 32.7c. A total of 437,036 tons was hoisted, of which 37,906 tons was sorted out as waste, assaying 0.807 dwt. per ton, leaving 399,130 tons milled, which carried 9.729 dwt. gold per ton, as deduced from actual bullion recovery plus assay value of mill tailing. The final tailing assayed 0.53 dwt. gold per ton, showing a recovery of 94.836%, which was slightly in excess of the theoretical extraction. The mill extraction was 65.597%, the cyanide sand extraction increased this by 22.551%, and slime extraction by 6.688%, making total cyanide recovery on original ore-value of 29.239%, the actual recoveries by cyanide being respectively 86.982 and 85.313%. The mill contains 200 stamps, which operated 322½ days, thus showing a duty of 6.183 tons per stamp per diem. The ore-treatment, or reduction, expenses were $1.106 per ton, made up as follows: ore-sorting 4.6c., crushing 4.6c., haulage 1.9c., stamp-milling 35.4c., tube-milling 13.1c., conveyance, classification of pulp and filling 5c., cyaniding 31.5c., disposal of tailing 13.2c. Total receipts were $9.29 per ton, total costs $5.42, and working profit $3.87 per ton.

OOREGUM GOLD MINING CO., MYSORE, INDIA.

The Ooregum Gold Mining Co., during the year 1907 treated in its 120-stamp mill 124,160 tons of ore, which yielded 64,084 oz. fine gold. Re treatment of 89,164 tons of tailing by the cyanide process produced 9068 oz. gold, and, with the addition of 410 oz. obtained in the dismantlement of the old No. 3 mill, the total bullion produced was 73,562 oz. The average yield was 0.5166 oz. gold per ton. The tailing produced 0.102 oz. per ton. The gold yielded a return of £278,898, from which a royalty of £13,827 was deducted, leaving net proceeds of £265,071. Miscellaneous receipts swelled the total to £267,888. As against this sum were expenses amounting to £173,433, so that the profit on the year's operation was £94,454. A portion of this was applied to the purchase of new equipment, and out of a balance of £40,922 dividends were declared at the rate of 17½% on preferred shares and 7½% on ordinary shares, amounting to £38,353. Dividends paid to date, since the first dividend, in April, 1891, reach the handsome total of £1,501,950, and the total receipts for the same period were £4,537,338. The issued capital is £300,041, on an authorized capital of £410,000.

Development work amounted to 18,394 ft., and the ore reserves at the end of the year were estimated at 143,988 tons, being a little more than one year's supply for the mill. The stock of tailing on hand amounts to 70,000 tons. The cyanide treatment showed a recovery of 67.5%, reducing the sand from an original gold tenor of 0.129 oz. to 0.042 oz., with a consumption of 0.63 lb. KCy, 0.68 lb. NaOH, and 0.12 lb. Zn per ton. Further milling details are not given. The Ooregum mine is one that is particularly subject to 'air blasts,' often involving great peril to the workmen.

CIA. LA UNION, PACHUCA, MEXICO.

The annual report of the directors of the Cia. Beneficiadora de Metales "La Union," for the year 1907, announces a decrease in the earnings due to four causes, imperfect work of the ball-mills, frequent demurrage of plant from interruption of the electric-power service, fall in the price of silver, and decline in the assay value of the ore. The use of the ball-mill presents a certain advantage in connection with the barrel amalgamation process employed, owing to the abrasion of iron from the balls, which supplies a necessary reagent in the chemical processes involved. But an excess of iron impedes the reactions, and increases the consumption of copper sulphate, and the ball-mills at this plant have contributed an enormous excess of iron to the pulp. The milling-cost with ball-mills has been ₱1.53 per ton, as against 80cv. with the Chilean mills working alongside. The tonnage crushed by ball-mills during the year having been 11,547, a saving of ₱17,666 would have been effected by using Chilean mills exclusively. Similarly, the company has made comparisons between the barrel-amalgamation and the cyanide methods of treatment, demonstrating that by amalgamation a recovery of ₱34.40 of the silver and ₱2.75 of the gold was regularly obtainable, while, in parallel, cyanidation yielded ₱30 of the silver and ₱4.50 of the gold, the total recovery standing at ₱37.15 and ₱34.50, in favor of barrel-amalgamation. But a comparison of costs shows ₱13 per ton by amalgamation against ₱8 by cyanidation, so that a net gain of ₱2.35 per ton would result from the introduction of the cyanide process. The company is accordingly making the necessary changes.

The affairs of the company are so prosperous that it expects to continue to meet these extraordinary expenses out of income without passing a dividend, if silver should fall no lower in price. The dividend distributed for the year has been ₱105,000, and there was expended on the installation of a cyanide plant ₱26,184, thus placing this property at the head of present producers at Pachuca, the next highest dividend-distribution by any mine in the district being ₱72,000. The total ore milled was 26,896 tons, which produced 28,055 kg. of fine silver, or 1.15 kg. silver per metric ton. The company had a contract with the Negociacion de San Rafael for the sale of its bullion, permitting settlement to be made at the election of "La Union," either on the Government exchange rate fixed monthly, or on the basis of New York silver quotations. The latter basis was chosen, resulting in a gain for the company over the returns that would have resulted by applying the Government rate.

DIRECT AIR-PRESSURE PUMPING.

During several months of the year 1907 an extended series of tests was made on a driven well near the plant of the Westinghouse Air Brake Co. at Wilmerding, Pa., to determine the amount of water raised, air required, and other necessary data relative to pumping by direct air-pressure. As wide a range of conditions as possible was covered in regard to different sizes of pipe and different combinations of 'lift' and 'submergence,' obtaining for each condition the most suitable and economical arrangement. The lift is the vertical distance from the water level in the well to the point at which the water is discharged. The submergence is the distance from the water-level down to the point in the well where air is admitted to the discharge pipe.

The well used is 174 ft. deep from the surface of the ground, has 6-in. casing, and the water-level is ordinarily from 16 to 20 ft. below the surface. An oil-well derrick was constructed over the well, with platforms at various heights to provide means for altering the lift. The air supply was obtained from a 1-in. connection to the air-system of the Westinghouse Air-Brake shops. The arrangement of piping, reservoirs, and so forth, is shown diagrammatically in Fig. 1. Two air-storage reservoirs, 30½ by 84 in., receive air from the supply source through a three-way cock, so that only one tank can be charged at a time. At the other end of these tanks, connection is made through a similar three-way cock to the line leading to the well. In this line was placed a 14 by 35-in. reservoir, a globe-

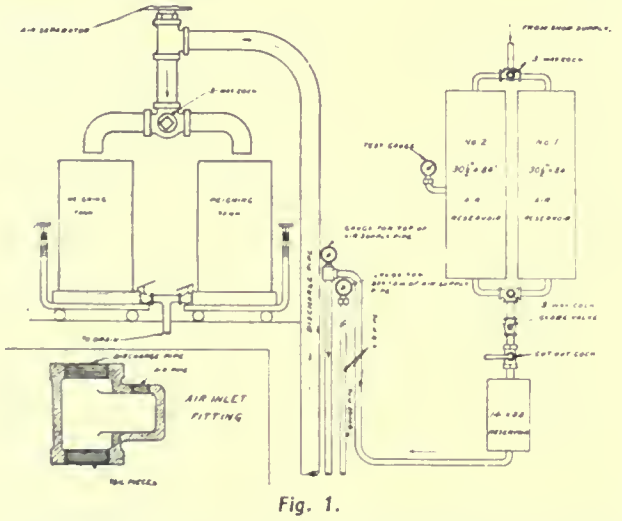


Fig. 1.

valve, and a cut-out cock. The shop air-system averages from 140 to 160 lb. pressure. Tank No. 2 was used for measuring the air in the tests, and tank No. 1 for starting the pumping operation.

Nearly 1800 tests were made, covering from 350 to 400 different combinations of discharge pipe, lift, and submergence. From t › figures obtained in these tests, curves were plotted, showing the variation of cubic feet of air used per gallon of water raised, and the gallons of water delivered per minute for the different ratios of lift to submergence. From these curves it was found that the cubic feet of air used per gallon of water raised, and the gallons of water delivered per minute, are practically the same for each ratio of lift to submergence for any submergence of a given size of discharge-pipe. For example, a lift of 10 ft. and a submergence of 20 ft. will take the same amount of air per gallon, or lift the same number of gallons per minute, as a lift of 100 ft. and a submergence of 200 ft., the size of discharge-pipe being the same. In both these cases the ratio is identical, while the submergence in the latter is ten times as great as that in the former. Consequently, it is only necessary to consider the ratio of lift to submergence and the size of discharge-pipe. It is also found that, for a given size of discharge-pipe the gallons of water raised per minute decrease as the ratio of lift to submergence increases. Also, the cubic feet of free air per gallon of water raised increase as the ratio increases for a given size of discharge-pipe, and, for a given ratio, the cubic feet raised decrease as the size of the discharge-pipe increases.

As regards the air-pressure required, it was found that the smallest pressure possible that would give a continuous flow from the well, was the proper pressure to use. It was found that, if the air-pressure was choked down slightly below this point the water would come out intermittently in spurts, and the air required per gallon was slightly less than the continuous flow, but the water delivered was considerably less. On the other hand, if the air-pressure was gradually increased above that just required to give a steady flow, the quantity of water delivered would increase somewhat, but the air per gallon increases in a greater

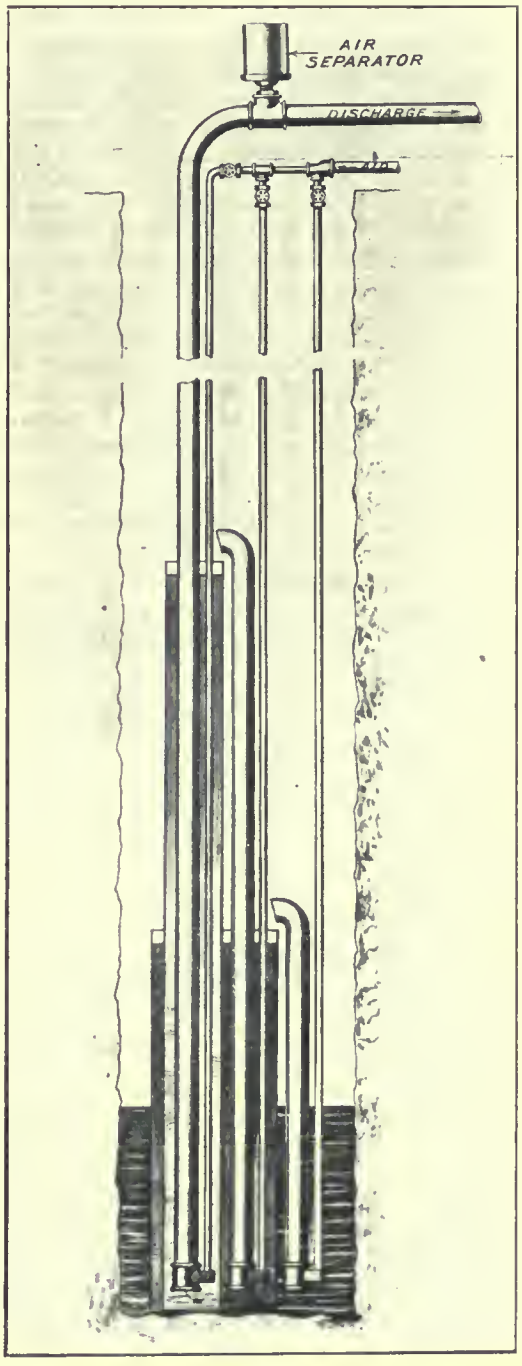

Fig. 2.

proportion, and as the air-pressure is further increased, the gain in the quantity of water delivered grows less, until at a certain point it stops, and from there on the water delivered decreases in amount. It is easy to regulate the air-supply by the sound of the discharge.

From the results obtained, it would appear that for a given lift the further down in the well the submergence is made the more economical the result would be. This is true as far as the well is concerned, but it must be considered that the greater the depth of the air-inlet, the greater the air-pressure must be, and consequently the more horsepower must be employed to compress the air. The quantity

of air required to operate the well decreases with the depth, while the horse-power required to compress a cubic foot of air increases as depth grows greater. A curve representing the horse-power per gallon of water raised for varying depths and constant lift will at first decrease as the depth increases, until it reaches a minimum, after which it increases.

The manner in which the operation occurs inside the well is as follows: As the compressed air enters the discharge-pipe at a pressure only slightly above the hydrostatic head, the column of water above is forced upward. Air continues to enter, filling up the space left by the rising body of water until the top of the water-column reaches the discharge opening. The moment that a portion of the rising water is discharged, the weight of the column is thereby reduced, and the air beneath it will correspondingly expand, thus reducing the pressure on the water in the discharge-pipe below the air-inlet. The weight of the water in the well, outside of the discharge-pipe, then forces the water upward into the pipe, stopping the inflow of air. The pressure in the air-supply pipe is quickly reinstated by its connection with the supply, so that it again forces an entrance into the discharge-pipe. This is repeated until the whole discharge pipe, above the air-inlet, is filled with alternate bodies of air and water, the combined weight of which is enough less than the water in the well to keep up a constant flow of water into the discharge-pipe. As each body of air rises, the total weight above it grows less, so that it continues to expand until, when it reaches the discharge, it issues at atmospheric pressure. In this way a continuous flow from the well is maintained as long as a sufficient quantity of air is supplied, and the capacity of the well is not over-taxed.

BOOKS RECEIVED.

TYPICAL STEEL RAILWAY BRIDGES. By W. Chase Thomson. Pp. 178. Ill. Engineering News Pub. Co., New York. 1908. For sale by the MINING AND SCIENTIFIC PRESS.

This book is exactly what its sub-title declares it to be, an elementary course for engineering students and draftsmen. It is particularly well adapted for such use. The designs of a number of the more common types of railroad bridges are worked out in detail, the treatment being such that a student with a working-knowledge of the strength of materials will be able to gain a comprehensive acquaintance with the leading features of bridge designing. The methods presented are thoroughly modern and according to approved practice. Five folding plates, illustrating the completed designs, add much to the usefulness of the book. This volume should be of especial value to the instructors who have not the time to prepare lectures themselves, or who do not care to use the more elaborate and lengthy treatises.

A POCKET HANDBOOK OF MINERALS. By G. Montague Butler. 8vo., pp. 298, insets and index. Ill. New York. John Wiley & Sons, 1908. Price $3. For sale by the MINING AND SCIENTIFIC PRESS.

The peculiar merit of this book is its size, admitting of being conveniently tucked in the pocket. Thus it can be made a companion in the field. It covers the more important mineral species with which the mining engineer has to deal, giving a sufficient description for identification. The minerals are arranged in accordance with the acid rather than with the base in the molecule, which has its advantages and also its manifest disadvantages in the absence of any means of tracing out all the minerals, let us say of copper or lead. There are tables for determination of species, atomic weights, and other useful information. The book is handsomely printed and bound.

A TEXT-BOOK OF ASSAYING. By C. and J. J. Beringer. 11th ed., pp. 456. London. Charles Griffin & Co. 1908. Price $3. For sale by the MINING AND SCIENTIFIC PRESS.

A TREATISE ON MINE SURVEYING. By Bennett H. Brough. 13th ed., pp. 372. London. Charles Griffin & Co. 1908. Price $2.50. For sale by the MINING AND SCIENTIFIC PRESS.

Brough's 'Surveying' is known to all students of mining, and has found a ready sale even in America, where numerous text-books on the same subject are available. This (the 13th) edition has been carefully revised, and contains descriptions of appliances invented since the publication of the 12th edition. Beringer's 'Assaying' is another of the well tried books on technology, and represents the authors' experience as teachers in the Camborne School of Mines, in Cornwall.

COMMERCIAL PARAGRAPHS.

O. P. CHERDON has resigned from Arthur Koppel Co., San Francisco, and leaves at once for the East and Europe. He expects to return within two months.

THE HENDRYX CYANIDE MACH. Co., Denver, has recently shipped a complete 100-ton cyanide plant to the Alvarado Gold Mining Co., Congress Jct., Arizona.

THE WESTERN LUBRICATING VALVE Co., Denver, has recently received an order for 300 Western lubricating valves, from the Homestake Mining Co., Lead, South Dakota.

THE COAST STATES CONSTRUCTION Co., San Francisco, has moved its office to the Hooker & Lent Bdg., Second and Market streets. George R. Devol will still be associated with Mr. Hopps on the engineering corps of this company.

THE ECLIPSE DRILL SHARPENING MACH. MFG. Co., Denver, have recently sold one of their machines to the Strong mine, Victor, Colo.; one to the Golden Cycle mine, Independence, Colo., and one to the Bunker Hill & Sullivan mine, Wardner, Idaho.

JAMES S. WATSON, manager of the drive chain department of the LINK BELT Co., has transferred his headquarters from the Philadelphia works to the company's chain manufacturing plant at Indianapolis, where he will combine supervision of manufacture with direction of the selling force.

THE HENDRIE & BOLTHOFF MFG. & SUPPLY Co., Denver, has issued its regular monthly announcement for June. It describes a number of specialties lately introduced, among them being waterproof leather belts, a new form of belt lacing, a washer and gasket cutter, and a combination pocket tool for miners. Special circulars describing each of these will be sent to any address.

THE RANSOME CONCRETE MACHINERY Co. has recently put on the market a device which combines a concrete barrow and mixer. The essential feature is a frame into which the the ordinary two-wheeled concrete cart is placed so that it may be revolved about the axle of the cart, the wheels serving as journals. The frame is provided with a cover which clamps on the cart, closing it tightly, and blades in the cart body secure more efficient mixing. The mixer may be hand or power driven, and in single or multiple parallel units.

THE PACIFIC TANK Co. will, on or about June 1, move its San Francisco office to 318 Market street. An exhibit of articles manufactured and handled will be maintained at the new location, and the management invites mining men to make its office their headquarters when in the city. A new 'Mining and Cyanide' catalogue, No. 7, issued by the company, will be ready for distribution June 1, and will be sent free of charge to anyone interested. The catalogue is an especially handsome one, embracing 128 pages, and includes, besides a description and illustration of all tanks, supplies, and accessories for sale by the company, numerous pages of tables and useful information.

BROKEN STEEL TAPES may be quickly mended by a repair kit recently put on the market by the Chicago Steel Tape Co. A thin metal sleeve, made to fit all widths and thicknesses of tapes, is coated on the inside with a composition of solder and flux which melts at so low a temperature that it makes a complete adhesion with the broken ends of the tape when heated by an ordinary match. This repair can be made in the field in a minute or two, without taking the temper out of the tape or obstructing its being coiled in the case. The splicing sleeves are put up in small round wooden boxes which hold several dozen sleeves and yet can be carried in a vest pocket.

MINING AND SCIENTIFIC PRESS

Whole No. 2500. VOLUME XCVI. Number 25. "Science has no enemy save the ignorant." THREE DOLLARS PER ANNUM Single Copies, Ten Cents.

MINING AND SCIENTIFIC PRESS

ESTABLISHED MAY 24, 1860.

PUBLISHED AT 667 HOWARD ST., SAN FRANCISCO.

Editorial.

THIS ISSUE of the MINING AND SCIENTIFIC PRESS rounds up to the goodly number of 2500 since it first appeared, a little over forty-eight years ago. By virtue of superiority in age, supported further by a record of dignity, ability, and honesty throughout this long career, it may consistently claim preeminence as dean of the periodicals devoted to mining in the Western World.

IN THE TEN YEARS between 1890 and 1900, the population of the United States increased from 62,947,714 to 75,994,575, and the estimate for 1907 was 85,532,761, or a gain of 36 per cent in 17 years. During this period the circulation of currency per inhabitant increased from $22.82 to $32.22, an increase of 41 per cent. The production of pig iron, which was 9,202,703 in 1890, rose to 25,781,361 tons in 1907, this being a gain of 180 per cent. These figures are eloquent.

THERE ARE 73 tube-mills in use on the Rand, in 28 different mills, and the employment of them for re-grinding the pulp issuing from the mortars has permitted an increase in stamp-duty, so that in 10 mills it is in excess of 7 tons, the maximum being 9.2 tons per stamp per day in the Luipaard's Vlei mill. This is a violent contrast to the old mills in Gilpin county, Colorado, where a duty of less than one ton was so long the best obtainable, when crushing fine and amalgamating inside the mortar.

OUR LONDON correspondent points out that America is far behind Great Britain both in legislative and customary recognition of the liability of employers in the case of accidents to workmen and in provision for their general welfare. The plan of granting vacations under pay to men working for daily wage, inaugurated by the great firm of Brunner, Mond & Co. as a means for improving the steady attendance of laborers, is in advance of anything embodied in the Field System. The results obtained are very remarkable, and demonstrate anew how responsive is human nature to the principle of reward for the continuous performance of duty, when the object is some specific prize to be won.

A PRACTICAL concession in the way of adjustment to business requirements is the cut in the price of steel made by the United States Steel Corporation on June 9. The important changes are: billets reduced from $28 per ton to $25, Pittsburg sheet bars from $29 per ton to $27, Pittsburg plates from $1.70 per 100 pounds to $1.60, structural iron from $1.70 per 100 pounds to $1.60, merchant pipe, a reduction of two points or $4 per ton, wire nails from $2.05 per 100 pounds to $1.95. This will encour-

age industry, for although the reduction is not great, in the aggregate it looms large, and will prove a substantial aid in the recovery of normal conditions. At least such was the view of the independent steel-producers at the instance of whom the United States Steel Corporation is said to have made the concession. The detrimental influence of a great monopoly, however, immediately comes to the front. Under normal competition buyers could forecast future prices with some degree of certainty. They surely would hesitate and buy sparingly in a declining market until bottom had apparently been touched. But the law of supply and demand is disturbed in its operation when a great corporation is able to dictate. The buyer demands a guarantee of fixed prices for a reasonable period of four to six months. Failing this he is compelled to buy only for the pressing necessities of the hour. The cut in prices, accordingly, is a concession, an adjustment to the requirements of trade, and will, of course, facilitate recovery of business activity, but it misses being a stimulus, because back of it lies not the governing power of natural law, but the irresponsible whim of a few individuals.

THAT COMFORTABLE word 'metasomatic' is evidently destined to yield prominence in mining geology to 'magmatic,' for the introduction of the idea of waters of magmatic origin as a factor in forming ore deposits has led already to many careless inferences and interpretations. For this reason we give especial welcome to the article by Mr. Lewis T. Wright on 'Diffusion as a Factor in Ore Deposition,' wherein he discusses and analyzes the true meaning of the physics of magmatic differentiation. The comparison with a copper slag is most suggestive and illustrates how practical metallurgy can illuminate geo-physics. Mr. Wright's further remarks in extension of the subject of diffusion as a phase of osmotic pressure and the transfer of minerals without actual circulation of solutions, which has been discussed in our columns before, will provoke careful thought among mining geologists. We are much indebted to him for a kind of article most likely to aid the cause of scientific enquiry, in which speculation is subordinated to the probabilities following from the application of the phenomena and laws of physical chemistry.

Revision of Mexican Mining Law.

THE mining laws of Mexico have long been noteworthy for their liberality. The foreign colony has, of course, found matter in them for complaint, but that is of relatively small moment. The Anglo-Saxon rarely adopts the country of his accidental residence; he insists upon being not simply an alien, but an exile, magnifying the virtues of home and blaming his hosts for their contentment with strange ways and laws. Except for criticism of Mexico the conversation of the 'exiles' in the lobbies of the Palace and the Guardiola hotels would lack piquancy. But the foreigner knows that he has been well treated in Mexico. He can denounce mines and *baldio* lands on equal terms with native-born citizens of the country; moreover he can apply for and obtain patent to mines and lands without relinquishing his foreign allegiance. The only limitation is that acceptance of this generous privilege, of a sort which is absolutely denied to aliens in the United States, carries with it submission to the jurisdiction of the Mexican courts in all civil obligations of every nature arising in connection with such property. In other words, being admitted to the enjoyment of the full property rights of a Mexican citizen without having to become naturalized, he may not, when in difficulties, play the baby and appeal to the diplomatic representatives of his country for special privileges and claim exemption from the law of the land. A foreign corporation may enter Mexico, after having obtained a certificate of incorporation from the State of registry, and having the certificate acknowledged in due form before the nearest Mexican consul; this certificate, naming the officers and directors, and the accredited agent or attorney of the company for Mexico, being required to be officially translated and protocolized. The stamp-tax having been paid on the authorized capital stock, the company can then transact business, acquire property, and obtain patent to mines and lands through its proper agent, the same as a Mexican corporation. Here again the Mexican law out-does that of the United States in liberality. Our Federal statutes permit aliens, either individuals or corporations, to locate mining claims, but not to acquire patent, except such alien be a *bona fide* resident of the United States, and upon ceasing to be a resident, the property must be conveyed within ten years to those competent to hold it under our laws. The State laws incline to greater liberality in according privileges to aliens than do the Federal statutes. This is a product of the spirit of rivalry, of competition, and of growth, the same spirit that prompted the enactment of liberal alien laws in Mexico and in nearly all Latin-American countries, which are richer in natural resources than in capital for exploiting them. The tightening of the lines in Mexico is a symptom of maturity and strength, not of antagonism and racial prejudice. It is unjust to a sister nation that has freely shared with us her birthright, to ascribe mean and petty motives when she feels strong enough to claim her prerogatives. Whether indeed she be fully able to stand upon her dignity in this matter is a query open to the challenge of opposite opinions, both in and out of Mexico. The remarks of Señor José L. Requeña, President of the Mexican Chamber of Mines, indicate that strong men think the time is not yet ripe for the Republic to limit the privileges of the alien. These are questions of policy which are more likely to be adjusted to the advantage of the beneficiary through generous discussion than by condemnation and abuse. We believe that the spirit of the proposed revision of law could not be better shown than by the fact that among the reforms is that of excluding alien attorneys from practice before the Mexican bar. No alien is admitted to the bar in the United States, nor in the British Empire, nor for that matter, in any first-class nation in the world. Let us be just.

The Amalgamated Report and Copper Costs.

THE great copper mining companies operating at Butte, Montana, persist in withholding information from the public concerning the details of their management. This means two things: that the details would not justify the management in the financial results obtained, and that the public is willing to bet on a copper faro game even when it has good reason to believe that the cards are dealt out of a 'brace-box.' Nevertheless, there is a growing tendency toward speculation rather than toward gambling in those mining stocks which may rightly be classed along with industrials, due regard being had for the necessity of amortization of capital. The Amalgamated and the Anaconda are essentially public corporations, unlike the Calumet & Hecla, which, though listed on the Boston Stock Exchange, is controlled as a close-corporation by four or five men. The Amalgamated and Anaconda reports just issued are superior examples of what mining reports should not be. No data are given by which an outsider may check the conclusions of the apologists in whose behoof these annual addresses to stockholders are made. In the report of the Amalgamated Copper Co. the falling off in earnings from $15,154,400 to $6,680,-557, or 56 per cent, from one year to the next, is explained by the misleading affirmation that in May, 1907, there was an unlimited demand for copper, the selling price at that time being about 25 cents per pound, and that this demand was "seriously affected by the severe financial depression throughout the country." Anyone closely in touch with the copper market knows that precisely in May, 1907, there was a conspicuous absence of buyers, and that the stocks of copper were piling up at such an alarming rate as to make a sharp recession of prices inevitable. Moreover, this condition of the market was a precursor of the financial crisis which followed as a storm five months later. Declining copper prices meanwhile indicated the approaching industrial depression with the fidelity of a falling barometer. The highest price touched by the metal was 26¼ cents, in March, 1907. This was purely artificial. There was no legitimate demand to warrant it. In May the quotations stood at 25¼ cents; in June a weakening to 24⅞ cents took place. In July Mr. Rogers returned from Europe, full of assurance to the public, but in practice revealing that he was not as wanting in wisdom as he seemed. The arrangement with Phelps, Dodge & Co. occurred almost immediately after, by which the great Arizona copper people undertook, in combination with the Butte producers, to fix a price of 22½ cents. This agreement in itself was sufficient to have precipitated a panic. The weakness of two of the greatest factors in the world's copper market, in the face of persistently high quotations for many months, and in the midst of boom times, was thereby revealed. It gave the lie to all announcements from Amalgamated headquarters of an active demand for copper, and it demonstrated moreover that these concerns could not in reality fix prices, as they presumed to do. The reduction naturally weakened the demand still further, and shortly afterward there was someone selling largely under the market, which immensely accelerated the downward movement. The price dropped to 18¼ cents in August, to 14⅞ in September, and to 12⅛ in October, by which time the signs of impending general financial disaster were conspicuous to the world. It must be noted that selling fell off in April, and that practically no sales were made during the period of shrinking prices. The European demand was enormously exaggerated, and the heavy exports of copper chronicled at the time were to a large extent taken by speculators, and remained threatening the market. It is evident that the Amalgamated officials count on ignorance, or lack of inquisitiveness, on the part of the stockholders when they dare to issue statements so directly in contravention of facts easily accessible to anyone.

prices realized by the great copper producers were by the Amalgamated Copper Company's fiscal year, ending April 30, 1908, was 20 cents. Actually the prices realized by the great copper producers was nearer 17 cents. The Calumet & Hecla averaged a better figure, due to its policy of avoiding accumulation of stocks, showing that it is more profitable to follow a market that is subject to normal economic laws of competition than to try to restrict it where absolute control cannot be obtained. The causes of failure on the part of the selling companies to realize the benefits which high prices presumably should give, were shortage and inefficiency of labor; high prices of material; treatment of lower-grade ores, running up the cost per pound of copper produced; extravagant enlargements of plant and great increases in mine-exploratory work; and the necessity imposed by over-production for carrying large stocks of metal far beyond the period of high prices.

Finally, a large factor in the increase of costs, not only of producing copper, but of all industrial operation, was the disorganization of the railroad transportation service throughout the country. The delay in forwarding cars was so extreme that consignments from the Middle States to Colorado common-points, which include Salt Lake and Butte, were generally about four months in transit. Not only did this add to the cost of conducting any enterprise, through the consequent delays and embarrassment of management, but it added directly to the outlay for freight through the graft which flush-times and traffic-demoralization fostered. The practice of tipping yard-masters and other railroad employees to forward cars became a wide-spread scandal. A company was incorporated in San Francisco for the purpose of tracing lost carload shipments and insuring prompt deliveries for a fixed fee per car, which depended, of course, upon collusion with those who had the power to facilitate or impede the movement of freight. This is perhaps a solitary example of incorporating and financing graft as a recognized industry—a fit offspring of protected bribery in this unfortunate city. So far as conditions in the United States are concerned, the railroad situation had much to do both with checking the development of industry, on which copper consumption depends, and with increasing the cost of the metal to the producers.

Personal.

ALBERT BURCH has gone to Arizona.

ROBERT T. HILL is at Goldfield, Nevada.

JOHN A. REID is at Stockton, California.

CARL HOFFMAN has returned to Mexico City.

CLIFFORD G. DENNIS was in San Francisco last week.

ALFRED J. G. SWINNEY has returned to London from India.

F. PERCY ROLFE is on his way from London to Colombia.

T. A. RICKARD sailed on June 19 from Seattle for Alaska.

P. G. HOLMS has removed from Mexico City to Guadalajara, Jalisco.

W. D. PIERCE, of Chihuahua, Mexico, was at Goldfield this week.

DONALD B. GILLIES was recently at Rhyolite and Tonopah, Nevada.

CHARLES W. GOODALE is in San Francisco in the course of a holiday trip.

JUAN FELIX BRANDES is at Parral, Mexico, and will soon visit San Francisco.

A. H. DOUGLAS, of Rawhide, Nevada, is spending a few days in San Francisco.

GEORGE MAINHART has resigned as manager of the Champion and Delhi mines, at Grass Valley.

H. G. MORRIS, formerly of Colorado, is now superintendent of the Florence mill, Goldfield, Nevada.

VICTOR C. HEIKES, of the U. S. Geological Survey, is visiting various mining districts of Nevada.

HOWARD D. SMITH, after spending a week at Rawhide, Nevada, has returned to San Francisco.

F. L. RANSOME is at Goldfield for the purpose of completing his survey of the Goldfield district.

F. LYNWOOD GARRISON, of Philadelphia, sailed from New York on the 17th for Colombia, South America.

FRANK J. BOOTH is here from western Chihuahua, Mexico, in search of information concerning gold dredging.

JOHN B. KIRCHEN has been appointed general manager of the Montgomery-Shoshone property at Rhyolite, Nevada.

WALTER NEAL, superintendent of the cyanide department of the Dos Estrellas mill, El Oro, Mexico, is in San Francisco.

E. N. ATKINS, of the firm of DEGOLIA & ATKINS, San Francisco, is examining mining property in Trinity county, California.

A. A. TALMAGE, for some years manager for the Bialsdell Co., is now Pacific Coast manager for the Pittsburgh-Salt Lake Oil Co., with offices at Los Angeles.

ALEXANDER LEGGAT has resumed practice as mining engineer, having resigned from the position of City Engineer of Butte, Montana. His offices will be at Butte.

ROBERT H. RICHARDS has returned to Boston from Missouri, where he has been engaged professionally. While there the University of Missouri conferred upon him the degree of Doctor of Laws. He was the guest of honor at a dinner given on June 6 at the University Club, Boston, in recognition of his forty years of teaching at the Massachusetts Institute of Technology.

L. VOGELSTEIN & CO., of New York, give the following figures of German consumption of foreign copper for the period January to April, 1908:

	Tons.
Imports of copper	56,533
Exports of copper	2,723
Consumption copper	53,810

as compared with consumption during the same period in 1907, of 36,255 tons. Of the above quantity 52,259 tons were imported from the United States.

General Mining News.

ALASKA.

The region around the Innoko river, a lower tributary of the Yukon, is the scene of a stampede, according to Associated Press dispatches. It is said 800 men from Fairbanks alone have gone to the scene of the strike, which was made last spring, and that freight and passenger accommodations on three steamers leaving there recently, were completely sold out.——The *City of Seattle* landed a large shipment of gold from southwestern Alaska, at Seattle, the first of the week. She is the first treasure ship of the season to reach port from Fairbanks by way of the Skagway route.——The first boat of the season has reached Nome, after a delay of nearly ten days spent in fighting ice and fogs in Bering Sea.

ARIZONA.

COCHISE COUNTY.

Louis W. Hill, president of the Great Northern railway, who is heavily interested in the Shattuck Mining Co., was in Douglas last week, and is authority for the statement that the smelter would be built and that actual construction would be started within three months.

GILA COUNTY.

The prospects in the Globe district continue to be quite satisfactory. Since the first of the month the Warrior Copper and the Superior & Boston have increased their ore shipments considerably, while the Gibson, United Globe, and Arizona Commercial are maintaining their tonnages. The Old Dominion has four furnaces in blast, and the production of copper for the current month promises to be in the neighborhood of 3,000,000 lb. The Old Dominion Co. will at an early date commence shipping sulphide ore from Dalton, Cal., to its smelter, the product being desirable on account of the high percentage of sulphur and iron it contains.——The Gardner shaft, which will develop the Iron King and Black Oxide claims, has reached a depth of 90 ft. and is going down at the rate of two feet per day. It has three compartments—two each 4 ft. 6 in. by 5 ft., and one 4 ft. 6 in. by 5 ft. 7 in.—and is one of the best constructed shafts in the Globe district.——A steel tank with a capacity of 20,000 gal., for the storage of oil, is being erected at the Great Eastern shaft.——The Gibson Copper Co. has abandoned work temporarily on the new vertical shaft and is developing on the fifth and sixth levels of the old shaft and making stations in the new. The new vertical shaft is between the third and fourth levels and is 250 ft. west of the old shaft.

MOHAVE COUNTY.

S. C. Bagg, of Gold Basin, has taken a lease and bond on the Golden Rule mine and the Cyclopic mill, and is to operate both.——G. B. Ayers has recently shipped an $8000 bar of bullion, being the clean-up of a two weeks' run on the mill-dumps at Goldroad. This gold is recovered by a method of spraying the dumps with cyanide solution and pumping back to the mill the percolations from the mass. There is practically no expense connected with the recovery, the process being entirely automatic.——The McCracken Mining Co. is building a telephone line from Yucca to the mines, a distance of 36 miles.

PINAL COUNTY.

The Lake Superior & Arizona Mining Co. has resumed operations at its plant at Superior and expects to use 100 miners at once.——The Eagle Mountain copper mine, on the south bank of the Gila, opposite the Ray mills, has been sold to a company of Wisconsin capitalists represented by T. H. McGrath. The same company has also purchased the south half of the Sultana National. Both of these properties are near the new station of Erman, which is on the Phoenix & Eastern railroad, one mile east of Kelvin.

YAVAPAI COUNTY.

The Monica will have 10 additional stamps dropping in its mill within the next 20 days, and the slime plant is nearly completed.——It is reported that the Mount Elliott Con. Mines Co., which owns a group of claims in the Bigbug district, one of them being the well known Dividend mine, will double the capacity of its existing 10-stamp mill, and put in a new air-compressor.

YUMA COUNTY.

A company has been organized to work the Cobrallo group of nine claims, in the Harcuvar mountains, nine miles northwest of Salome.

CALIFORNIA.

CALAVERAS COUNTY.

The Boston mine, two miles northeast of Mokelumne Hill, is lengthening its adit and expects to build a stamp-mill. Thos. McSorley is superintendent.——The Reiner gravel mine, at Altaville, is working three shifts in sinking, and a depth of 85 ft. has already been reached. A steam hoist has been installed.——The Flour Sack mine, at the head of Fishers gulch, has been taken over under lease by Joseph Hamby of Mokelumne Hill. This property is noted for arsenical sulphides and flakes of gold, and is an extension of the celebrated Mammoth mine, just across the river in Amador county.

Map of California.

NEVADA COUNTY.

(Special Correspondence).—An 18-in. vein of ore milling $27.50 per ton is exposed at the bottom of the shaft in the Midas. It is said the ore can be mined and milled at $7.50 per ton. Work will start immediately to sink the shaft and push developments.——The American M. & M. Co. is preparing to start work on an adit on the Watts gravel mine, at Snowden Hill. It will cut the bedrock at considerable depth below the old workings and is expected to develop a large body of gravel. The necessary buildings at the mine are practically completed.——Henry Goering and L. M. Clark, of Nevada City, have acquired a large area of placer ground at Round Mtn. The property has been developed by an 800 ft. adit, which will be extended 300 ft. farther. A company will be organized and stock sold to raise funds for extensive development. The property is located in the Washington district.——The Sierra Queen mine has been bonded to a company known as the Sierra Queen Con. G. M. Co. and will be extensively operated according to the present plans of the management. A 400-ft. shaft has been sunk on the property and considerable driving done. The

new company is an Arizona corporation, capitalized at $1,000,000. Clifford J. Graham is consulting engineer.——John McM. Ross and John Hall have completed their examination of the Champion and Delhi mines for an English syndicate. They have been engaged in the work six weeks.——A new underground hoist is being installed at the Delhi mine. The 20-stamp mill is running steadily on good ore.——The adit at the Native Son mine, near Blue Tenet, has been cleaned out and cross-cutting will be immediately started.——Active developments will be soon resumed at the old Richmond mine. The mine is situated near the Jenny Lind.

Grass Valley, June 15.

SAN BERNARDINO COUNTY.

The Fremont M., M. & D. Co., at Barstow, has recently installed a new engine and hoist and is now hoisting ore. The management proposes to erect a 10-stamp mill in the near future.——The new custom mill, at Daggett, is running at its full capacity.——A quantity of placer mining machinery is being shipped to the Coolgardie mining district, 20 miles north of Barstow.

SHASTA COUNTY.

The office and store-room of the Backbone mines, eight miles west of Kennett, burned last week, but will be rebuilt at once.——The Bracket mine, in the Lower Springs district, has been re-bonded to the same Eastern company which has heretofore held it.——The Balakiava mine, at Coram, which has recently resumed, is working 10 or 12 miners. One furnace of the new smelter will probably be blown in during the latter part of July, although the complete plant will not be running full blast until fall. The power plant is nearly completed.

SIERRA COUNTY.

The flume of the Last Resort mine, east of Downieville, is being repaired, preparatory to starting the assessment work.——Morrel & Rae have taken an option on the Tom Boy claim, two miles from Forrest. They have made a cash payment of $500 and let a contract to extend the adit to intersect the vein.——Fleming & Smith have taken an option on the Good Faith mine, at Downieville, and have started work on it.

TEHAMA COUNTY.

It is probable that the California & Massachusetts Copper Mining Co. will resume work at its property on Tom Head mountain.

TUOLUMNE COUNTY.

The Harvard mill, at Jamestown, will start 10 additional stamps dropping this week, making a total of 50.——The Big Four mine, one-half mile east of Tuolumne, reports the finding of a 15-in. vein bearing free gold.——Operations were resumed last week at the Sierra Lime & Cement factory, south of Sonoma.——The Riverside mine, above Soulsbyville, is to re-open.——The Omega mill is nearly completed and the tramway between it and the main shaft is ready for service.——The shafts of the Wild Cat, above Soulsbyville, are being cleaned out and hoisting machinery installed, preparatory to starting development.——The bond on the Ida Klein mine, in Yorktown gulch, has been extended for 30 days, and underground work is to be started.——J. L. Tonkin has bonded his Wet Gulch property, three miles northeast of Columbia, to Remington & Ivy, of Seattle. The shaft is 135 ft. deep, the orebody at that depth is 3 ft. wide and assays $20 per ton in gold.

COLORADO.

CHAFFEE COUNTY.

Work has been started on a new smelter at Buena Vista. The project is being financed by capital of that city, Salida, and Denver, and ground for the plant was broken last week. It is expected that the buildings will be completed and the machinery in operation about the first of the year. The smelter will handle lead ores.

CLEAR CREEK COUNTY.

(Special Correspondence).—Carlson & Co., leasing through the Sidney adit, have sold their privileges to the East Argentine M. Co. A big force of men is to be worked in extending the drift and stoping. The orebody measures from 18 in. to 3 ft. wide, and assays $70 per ton in silver and lead.——J. J. White has taken a bond and lease on the Princess of India adit and group of claims, on Columbia Mtn., the bond calling for $30,000, with a payment of $10,000 being due one year from date. Mr. White will transfer his privileges to Jas. A. Mears, who recently purchased the American Sisters mine. The Princess of India adit, now in 800 ft., is to be advanced 1000 ft. to intersect the American Sisters vein at an increased depth of 600 ft. under the present deepest workings of that property. A compressor plant is to be installed at once, and the machinery will be on the ground within 30 days. It is understood that the American Sisters holdings are to be consolidated with those of the Accord M. & M. Co., operating a large group of claims on Saxon Mtn. S. Peacock has been appointed general manager.——More ore is being delivered at the local sampler at present than at any time since the panic of 1893. During the last week the average returns received from the product milled was 1.23 oz. gold, 22½ oz. silver, and 36.39% lead.——An enormous body of ore has just been uncovered on the Independence vein, intersected through the Tobin adit workings. The smelting streak is from 3 to 4 ft. wide, and 6 to 7 ft. of mill dirt alongside shows assays of 1.14 oz. gold, 35 oz. silver, and 11% copper. It will be necessary to mill the entire product as a smelting ore, for the reason that the mill located near the Wilcox adit is equipped only for the handling of lead-silver-zinc ores.——A body of $75 smelting ore 3 ft. wide has been struck on the Paymaster vein, cut 3600 ft. from the Wilcox adit entrance. The ore is a heavy lead, and driving is now in progress for the opening of the ground to permit of stoping.——Ericson & Anderson, leasing in the upper workings of the Seven-Thirty mine, have encountered a streak of high-grade ore in the extension of the drift westerly. The initial shipment gave returns of 340 oz. silver per ton. By continuing the drift for 100 ft. the heading will cut directly above the ground being operated by Luizetti & Co., who have been maintaining shipments of high-grade ore for over a year past.——An electric trolley system is to be installed at once at the Capital mines, near Georgetown.——The aerial tramway constructed from the Seven-Thirty dumps, the terminus of which is at the Pelican mill, was put into commission last week. The ore is being delivered at the bins and there is ample material now available for the running of the concentrator, which will be started next week.——Raising has been started from the Joplin adit to connect with the Gambetta shaft workings, a distance of 380 ft. After going up 20 ft. the shoot is still in evidence, the ore assaying 2 oz. gold, 50 oz. silver, and 62% lead.——George S. Wilkie, of Idaho Springs, has been engaged to make a number of tests at the Stanley mill upon ore from that property. The mill is to be enlarged and constructed along lines calculated to produce the greatest efficiency.

Georgetown, June 15.

EL PASO COUNTY.

The Cottonwood Coal & Power Co. has been incorporated at Colorado Springs to do a general coal business. The company owns 320 acres of coal land adjoining that of the Pikes Peak Fuel Company.

LAKE COUNTY.

(Special Correspondence).—The total production of the Leadville district for the month of May amounted to approximately 70,000 tons, or an increase of 5000 tons over the preceding month. Although many small properties have resumed since the financial flurry last fall, several large mines are still idle.——The shaft on the Forepaugh mine has been re-timbered and a new shaft-house will be built before operations are resumed. The old shaft-house was destroyed last fall by fire.——A number of old properties on Fryer hill are resuming, owing to the demand of the smelters for iron ores for fluxing.——The newly discovered orebodies in the Across the Ocean property, on Breece hill, will be developed through a new shaft which the company is now sinking. An entirely new equipment will be installed

by T. J. Gilroy.——After a protracted period of development, involving the sinking of the shaft and driving a drift to the old ore-shoot, the Silent Friend has opened what is probably the largest body of ore it has ever shown. Shipments at the rate of 1000 tons per month are in progress. Apparently the ore is of the same high character as that mined in the past.——Arrangements are being made for extensive placer operations on the old Derry ranch, between Leadville and Twin Lakes.——The recent strike on the Clipper property, south of the city in Hayden gulch, has created considerable interest. The Clipper is an extension of the Mayflower, which was an important producer for more than twenty years.

Leadville, June 15.

The Ballard, on Breece hill, at Leadville, is to open soon. This property has been the subject of much litigation in the past, and has been a large producer of bismuth.——There has recently been a revival of the discussion of the proposed tunnel that is to cut Mosquito range, connecting the Park county side with Lake county, at a point not far from Leadville.——Arrangements are being made to build a dredge on the Mekka placer, near Breckenridge.——The Hellena, in Iowa gulch, is being put in shape to begin operations on an extensive scale. The shaft is 600 ft. deep and it is necessary to pump 200 gal. per minute in order to keep it dry.

SAN JUAN COUNTY.

Shipments of concentrates from the Silverton district for the month of May were as follows: Silver Lake, 2100 tons; Gold King, 2000; Hercules, 575; Sunnyside, 250; Old Hundred, 50; Hamlet, 50. The following are the shipments of ore: Shenandoah-Dives, 250 tons; Highland Mary, 50; Detroit-Colorado, 25 tons.——The Domingo adit, near Eureka, is being put in shape for operation.

TELLER COUNTY.

The Gold Coin and the Granite properties shipped a total of approximately 100 cars during the month of May.——The Northwestern Iowa M. & M. Co., operating several claims on the south slope of Trail Mtn., 5 miles south of Victor, will resume at once. There is a 75-ton cyanide mill on the property.——A leasing company has been formed to work the Prinsett properties, which include a large number of claims in the Cripple Creek district. The life of the lease is three years. Operations will be started soon, and will be carried on through the Moffat tunnel under Gold hill.——May & Jenkins, lessees on block four of the Ajax Gold Mining Co.'s property on Battle Mtn., are installing an electric hoist and will soon commence to hoist ore.

IDAHO.

BOISE COUNTY.

The Boulder mill has been started, running on ore from the Mollie McCarty mine, one of the Boulder group. The ore is being transported by the new tramway, recently completed.—Suydam & Balbach have thrown up their lease on the Washington mine, on account of lack of capital.——Peter Reichert is to work a small vein of free-gold ore which he has recently discovered on Lost creek, 28 miles northeast of Idaho City. The vein is from 1½ to 3 in. wide, but assays $1100 per ton.

IDAHO COUNTY.

(Special Correspondence).—A rich strike on the Snow Storm mine, in the Elk City district, has caused some excitement there. The ore was taken from the bottom of the lower adit, about 110 ft. from the portal, and contains free gold.——The Hush placer mine has made its first clean-up, representing 20 days mining, the amount of which is not made public. This is one of the newer mines now under active development, and it has been improved recently with flumes and ditches.——The shaft being sunk in the Buster mine from the 300-ft. level is down 50 ft., and is reported to have struck the contact with the vein. The Buster is making regular clean-ups, and is so far the largest and most steadily worked property in the district.——Material, supplies, and new equipment are being sent to the Blue Jacket mine, on Salmon river, where the driving of a new adit will be started soon. There is already a 1000-ft. adit connected with a 500-ft. shaft. The new adit will start 250 ft. below the other, to test the depth of the orebody.

Elk City, June 13.

SHOSHONE COUNTY.

(Special Correspondence).—The Snowstorm mine, at Mullan, has stopped breaking ore because of a shortage of cars. The floods have shut off the supply and it is doubtful when more can be supplied. The Hunter mine is also curtailing its force.——A report from Wardner states that the Stewart, Mr. Heinze's mine, is to be re-opened, and that supplies are being laid in.——The management of the Star mine states that development will be continued during the summer, with as large a crew as can be advantageously worked, on the 800-ft. level, and that the company will erect a mill of its own next year if sufficient ore reserves are opened up. A crew of 18 men is now at work.——The Hercules mine now employs about 250 men, breaking ore on the second, third, and fourth levels. During the month of May 23,000

The Coeur d'Alene, Idaho.

tons of ore were shipped, most of which went to the East Helena smelter.——The Tamarack & Chesapeake has again put three machines in operation and will also use a crew of hand-drillers in developing.

Wardner, June 16.

WASHINGTON COUNTY.

The Wilson-Pack Co. report a strike of rich free-gold ore, at its claims on Hornet creek, 15 miles from Council. The owners claim to have a large vein at a depth of 30 ft. which assays $20 per ton.——The Pueblo & Columbia mines, in the Big Creek district, has increased the force of men by 10, making a total of 30 now employed.

KANSAS.

CHEROKEE COUNTY.

(Special Correspondence).—A rich lead strike was made in the shaft being sunk by the Luther Mining Co. at Baxter Springs, south of the Omaha mill. The ore was struck at 50 ft. and the drifts show a 12-ft. face. This is the same run as that found in the Lancaster, south of the Luther. This makes four adjoining properties showing a rich run of ore, proving that this part of the camp is underlaid with a fine orebody.——The Hawkeye mine is producing six to eight tons of concentrates per shift, nearly half of which is

lead ore.——The Heap-O'Brien mine shows a 30-ft. face of zinc-blende and galena. A new mill is to be installed at once.——Ore has been struck on the Catholic 'forty' by Robert McKay. He is at present pumping the property and pushing development work. Ore was struck at 118 ft. and continued to 152 ft. This is one of the deepest ore-beds encountered in the Baxter Springs camp.——The Eastman Investment Co. has been doing extensive development work. Twenty-elght drill-holes have been put down, and two shafts are now down to the orebody, furnishing about 150 tons per day to the White Eagle mill. The machinery of the plant has recently been overhauled and additional jigs and tables installed, which will increase the tonnage of the mill. A third shaft will be sunk in the near future.—— Work on the Big Chief mill is being pushed and it is hoped that it will be completed by July 1. Development work has advanced to such a point that the mill can be kept in steady operation as soon as completed. The orebody struck here is the same as that found on the Mission lease, and shows a 30-ft. face.——Preparations are under way for the re-opening of the Cave Springs camp, which has been idle for some time and was at one time the leading producer of the Joplin district. The Murdock-McCullagh Mining Co., of Galena, has taken over the lease upon the tract and will drain the main part of the camp.——The Victoria mill, on the New Century lease, is being torn down for removal to the Delta lease, in the same locality. About five weeks will be required for the removal and re-construction of the plant.

Galena, June 15.

NEVADA.

CHURCHILL COUNTY.

A movement is on foot to establish a power station at Chalk Mtn., half way between Wonder and Fairview. It is planned to transmit the power from the headwaters of the Carson river in Alpine county, California, 140 miles distant. P. H. McLaughlin, of Fairview, and H. J. Darling, of Reno, are interested.——Development on the IXL mine, about twenty miles from Wonder, is to be resumed.——The Gibraltar Investment Co., of Denver, has secured control of the Queen group of claims, in the Wonder district.

ESMERALDA COUNTY.

(Special Correspondence).—The new mill of the Homestake Mining Co., near Rhyolite, is ready to start. The plant has 25 stamps of 1050 lb. each, 3 tube-mills, with amalgamating plates following both stamps and tube-mills. The mill will have a capacity of 125 tons per day and will be operated by electric power. At the mine, a new Ingersoll-Rand air-compressor, driven by a 60-hp. Western gasoline engine, supplies power for three Ingersoll and three Waugh drills.——The Montgomery-Shoshone, at Rhyolite, is mining and milling 150 tons of ore per day, the extraction in the mill being about 87%. This recovery is divided about equally between concentration and cyanide treatment. The mill is operated by electric motors and the hoisting engines and compressor by steam. The main shaft has reached a depth of 700 ft. The water being pumped from it amounts to 75,000 gallons per day.——Rich ore has recently been struck on the 400-ft. level of the Tramp Consolidated at Rhyolite.

Goldfield, June 16.

The Rogers-Syndicate lease will probably exceed the wonderful production of the Little Florence, its neighbor to the north. There has already been distributed as dividends $185,000, and it is expected that before the lease expires, on June 11, at least one-third of a million dollars will be divided among the shareholders.——A company of New York men, headed by E. W. Gillette of the L. V. & T. railway, has secured a lease on a block of ground 600 ft. square, belonging to the Goldfield Rochester Mining Co. The lessees will begin work soon.——The Albemarle has started crosscutting at a depth of 310 ft.——The Goldfield Red King Claim Leasing Co. has cut two veins in the drift at the 450-ft. level of the Red King claim on the Florence ground. A 50-hp. hoist has been installed and power-drills will be used.——F. H. Vahrenkamp has taken a lease on the Conqueror ground.——Fifty-five lessees are at work in the new camp of Granite, 8 miles west of Schurz. The town boasts a population of 250 people, and prospects for a producing camp are bright.——The Little Florence this week won its point against the Goldfield Florence in the action growing out of the charge against the former of unworkmanlike development of the mine under the Little Florence lease. The Goldfield Florence is ordered by Judge Langan to impound the money, some $170,000, involved in the litigation, sustaining the Little Florence motion, which was made on the ground that the property in dispute was being shipped to Denver.——The Goldfield mines produced, during the week ending June 12, a total of 2673 tons, valued at $195,360. The Tonopah mines, for the same period, produced 5758 tons, of an estimated value of $118,680.

HUMBOLDT COUNTY.

A two-compartment shaft will be sunk on the Therein property, in Seven Troughs canyon.——Gilliam & Scott, Minneapolis capitalists, have secured control of the Prior & Chadbourne lease on the Mazuma Hills estate.——The hoisting equipment of the Seven Troughs Florence Mining & Leasing Co., operating the Harris lease on the property of the Seven Troughs Mining Co., near Vernon, arrived in Lovelock, the nearest railroad point, last week, and is now being hauled to the lease. The equipment includes a 15-hp. Foos-Fulton gasoline hoist, head-frame, buckets, cars, and the like.

NYE COUNTY.

The Tramp Con. has made a strike of rich ore on the 350-ft. level of the Denver claim.——The Greenwater & Death Valley, the property of Charles M. Schwab, has struck copper ore assaying as high as 20%, at the 1000-ft. level of the shaft.——Parker & Keller have taken a lease on the Base Mtn. property of the Skookum Bullfrog Mining Co. and have already started work. The adit, now in 350 ft., will be extended to cut the vein at a vertical depth of 350 ft. The Skookum is two miles east of the Diamond Queen.—— The Round Mountain Mining Co. has uncovered an orebody which, it is claimed, is 160 ft. wide, and 20 ft. of that width will assay $100 per ton in gold.——The new hoisting plant at the Buckeye, east of Tonopah, is completed and sinking will be resumed. The shaft is now 300 ft. deep.

LINCOLN COUNTY.

H. A. de Rudio has taken a bond on the Ivanpah property, in the Ivanpah district, 50 miles west of Searchlight. The property consists of three groups of claims, on all of which are tungsten ore. Work has been started preparing a trial shipment, which will be sent out by way of Calavada, a station on the Salt Lake railway, 10 miles distant.

WHITE PINE COUNTY.

The 300-hp. electric hoist of the Veteran mine was tested last week and was found to work satisfactorily. The power comes from the smelter at McGill, a distance of 20 miles. ——It is expected that work will be started in a short time on the Hidden Treasure group, lying west from Lane City, and joining the Nevada Con.——D. C. McDonald, manager of the Success mine, of the Duck Creek district, has eight men employed completing the work necessary to be done before patents can be obtained.——A whim has been erected on the Sunlight claim, at the main shaft, which was 60 ft. deep, and it will be sunk deeper.

MICHIGAN.

The Keweenaw will start a second shaft near Medora this week. The equipment is on the ground. The rock-house has been completed at the Medora shaft. Sinking has been discontinued temporarily and drills used in driving.——The Mohawk mineral output for May, 607 tons, was the largest, with one exception, for any like period in the history of the company.——Grading for the railroad to the No. 5 Isle Royale shaft is practically completed, but the shaft is not ready to produce because of having 'lost' the lode. The shaft is down about 350 ft., and in the course of sinking it is expected that the lode will heave back to the shaft before the fourth level is reached. Four drills are ruuning.

MISSOURI.

JASPER COUNTY.

(Special Correspondence).—The output of the Missouri-Kansas district is still somewhat curtailed on account of the rains and flooded streams. Many of the mines, along the water courses, have installed extra pumping plants and are overcoming the water, and the output will soon be normal. The price of lead ore is still on the increase, while zinc remains stationary.——A company of Joplin men have organized the Hanover Mining Co., capitalized at $100,000, to develope a 36-acre lease on the Connor land, south of Carterville. The new lease has been carefully tested, 14 drill-holes having been sunk, all of them striking the same run of ore. One shaft has been completed to the orebody, a distance of 217 ft. While sinking the shaft a number of cross-drifts were run. Plans have been made for the erection of a 200-ton mill in the near future.——The Hennessey Mining Co. has been re-organized and has taken over the old Anderson mine and mill, at Chitwood. New machinery will be installed and the property put on a producing basis at once.——The Lizzie D. Mining Co. has been organized at Joplin, with a capital stock of $48,000. The company has a lease of 17 acres on the Malang-Matthews land, at Peacock. Six drill-holes have been sunk, all striking ore. A shaft has been sunk and ore found at 173 ft. The shaft is still in ore at 188 ft. A new boiler and pump have been installed.——The McMillan Mining Co. is making preparations to operate extensively at Four Corners, northwest of Joplin. This company holds a lease on ten lots upon which there is a large amount of mine equipment. The new company will add to this and develop the lease.——Another feature of the spring development in the district is the number of new mills being erected and remodeled. A. L. Shepard of Chicago has just completed the third mill since the first of January. The three mills represent an investment of $100,000, and are all situated along Center creek, north of Webb City. The latest is the Corrie Cole mill, on the Beasley lease. It is a 200-ton plant and made its initial run of 50,000 lb. of zinc and 30,000 lb. of lead a few days ago. The mine is in soft ground and has been a good producer for some time. Another mill owned by Mr. Shepard is immediately north of the Corrie Cole, also of 200 tons capacity and operating on the same run of ore as that worked in the famous Kansas City-Bradford mine. The third is the Sturgis mill, which was completed a few weeks ago and has been active since.——The Lehigh Zinc Co. is building a 150-ton mill on their property at Lehigh. There are 22 acres in the lease, which is already well developed. Two shafts have been sunk, one down 85 ft., which has already penetrated 22 ft. of ore. The same company holds a ten-acre lease across the creek, on the Moler-Smith ground on which there is a 98-ft. shaft. The company holds another lease at Cottonwood Springs, where an orebody 50 ft. thick has been struck at a depth of 165 ft. ——Three new mills are being built for the sheet-ground camp, north of Webb City. Ball & Gunning have finished a 250-ton mill on the Bird Dog lease, and expect to have it in operation in a fortnight. The shaft is in sheet ground and is 225 ft. deep.——The Moark-Nemo Con. Mining Co. is erecting two 350-ton plants on the Guinn and Aylor lands. There are two 125-hp. gas engines and one Corliss compressor. Two Foust automatic jigs will be installed.——The Yellow Dog mine, north of Webb City, is sinking its third incline shaft. The new shaft will handle the ore from both the upper and lower runs. There are only two other incline shafts in the district, one being sunk on the Continental lease by the Tamagama Mining Co., in the Joplin camp, and the other already in operation in the Cave Springs camp.——The Granby Mining & Smelting Co., one of the largest in the district, is re-opening all the mines on its properties. Eight mills are already in operation and four drills are prospecting. The Gravity tailing mill and the Burress sludge mill are also operating on the Granby land. The Golden Rod, another Granby plant, is temporarily closed pending development. The third hole is being drilled and is now 70 ft. deep. One hole penetrated an ore-body 20 ft. thick.——One of the richest lead strikes made lately, was reported from the Log Cabin mine at Duenweg, at a depth of 154 ft. A number of mines in the vicinity have been operating on galena at 50 ft., but are now making preparations to sink deeper to strike the run encountered in the Log Cabin shaft.——A rich run of zinc-blende and galena was found in the Next Week mine, at Bellville, on the old Liverpool lease. The top of the run has not yet been discovered as the find was made by driving from the 96-ft. level. Enough work has been done, however, to show that the body is large and unusually rich. The ore is being cleaned on hand jigs, and some of it is in large chunks and ready for the market when taken out.——There is a great deal of activity in the camp west of Joplin. The Bull Frog mine is producing from 80 to 100 tons per week. The Grace mine has secured a lease upon 40 acres east of its own property and will begin prospecting at once. The Monitor mine, which has been closed down for some time on account of water, has installed pumping machinery and will be able to resume work in a short time.——The Spring City camp, south of Joplin, is also active. The new Delta mill is almost completed and operations will be begun as soon as the shaft is unwatered. A rich deposit of lead ore has been discovered, which the company will develop. Three drill-holes are in ore and the shaft is down to the 160-ft. level.——The Sunrise Co., in the same camp, has recently installed a crushing plant, and the past week produced 12 tons of zinc and 4000 lb. lead on four hand-jigs.

Joplin, June 15.

UTAH.

SALT LAKE COUNTY.

The Bingham Great Western Mining Co. has been incorporated to exploit a group of claims in the West Mountain district, Bingham canyon.——The Starless mill, at Bingham canyon, which was demolished last spring, will be rebuilt at once.——The Butler shaft of the Butler Liberal is in shape to start sinking. It is the intention to sink at least 50 ft., so that the extent of the orebody can be determined.

SUMMIT COUNTY.

It seems an assured fact that the Daly-West will resume in the near future.——The force at the Silver King Coalition mine and mill is slowly but steadily being increased. The King is to purchase the Jupiter holdings, and thus increase the area of its property 113 acres.——The Nelson-Queen, in the Elkhorn district, is to resume, and preparatory to extensive development has purchased new boilers, an engine, cages, and other minor equipment.——Numerous improvements are under way at the Daly Judge mill, including the building of a conveyor system. It is possible that the force at the mine will be increased, which would necessitate another shift at the mill.——It is understood preparations are being made for the resumption of work at the Keystone property in Thaynes canyon.——The final work in the cleaning up of the cave in the Ontario drain adit between shafts No. 2 and 3 was accomplished last week and now the big waterway is permanently open.

MEXICO.

The Cia. Metalúrgica y Refinadoro del Pacifico, at Fundicion, Sonora, has made its first shipment of matte to New York. The consignment was three carloads, and went to the Nicholls Copper Co.——The Mexican Exploration & Mining Co. has exercised the option which it has had for some time upon the Zapal gold mine in Mexico. The mine is one that has been worked for several years by its former owners, who are Mexicans, but who have never developed it to its full capacity. During the past three months the Mexican Exploration & Mining Co. has kept one of its engineers at the mine making examinations and assays; also supervising the sale and shipment of ores.——W. E. Bruyn has secured an option on the San Jose de Gracia mine in the Sierra Juarez district of Oaxaca, and is working the property. Power-drills have been installed. The mine and mill are connected by an aerial tramway and 3500 ft. of surface track.

Special Correspondence.

LONDON.

United Alkali Co.—Brunner, Mond & Co.—Methods of Encouraging Workmen.—Employers' Liability.

A few weeks ago I gave some particulars of the United Alkali Co., the great chemical consolidation in the North of England. This week I am able to give similar details in connection with the other great chemical firm, Brunner, Mond & Co., of Northwich and elsewhere. The chemical industry generally settles in a locality where fuel, brine, and pyrite are cheap. Northwich is in the centre of the Cheshire saltfield. There are coalfields on all sides, in Lancashire, Staffordshire, and North Wales; while Spanish pyrite is imported to Liverpool and thence by the Weaver canal. Many of the chemical works belonging to the United Alkali Co. are found in the same district, at Runcorn, Widnes, and St. Helen's. Brunner, Mond & Co. differs from the United Alkali Co. in that it is a gigantic business that has gradually grown from small beginnings, instead of being a consolidation of a great number of businesses. There is another difference as well, for the finances are managed in an entirely different manner. When the United Alkali Co. was floated, the highest possible purchase price was exacted, with the consequence that the capital is top-heavy, being very nearly £9,000,000. At the time of flotation the chemical trade was booming, and the prospective profits were quite unjustifiably figured on the basis of the current profits. So we see ordinary shares getting little or nothing nowadays, and the preference shares not forming the best of security, seeing that there are three million pounds worth of debentures in front of them. The year 1907 was a comparatively good one for the United Alkali Co., but out of £479,349 profit, the three million ordinary shares only received £56,875 dividend. Not only is this over-capitalization unsatisfactory to the shareholders, but it prevents the company from ever raising any more funds for capital extension.

As a contrast to this, the financial position of Brunner, Mond & Co. is cheerfulness itself. The total paid up capital is £2,789,650, two-thirds of which is in ordinary shares and one-third in 7% preference shares, and there are no debentures whatever. Not only so, but the company also has in hand a reserve fund of £900,000, most of which is in first-class investments. Three years ago, when it was desired to place some of the reserve fund, which then stood at one million pounds, into the business as an extension of capital, £500,000 was paid out to the general trading account and corresponding new ordinary shares issued to shareholders at par as a bonus. The profits of the company during the year ended March 31 last amounted to £740,951, which is considerably more than the yearly profit of the United Alkali Co. Of this sum £100,000 is placed to reserve, $54,980 is paid as preference dividend, and $588,861 as ordinary dividend, which is at the rate of 30% per annum. The profit for the year was a trifle less than that for the preceding year, which was £778,500, the fall being due to the increased cost of coal. Until now there has always been a regular increase in the profits. Ten years ago the profit was £367,400, which shows how the business has increased during recent years. The firm of Brunner, Mond & Co. shows its sagacity in many ways. For instance, if there is a new process which holds out considerable promise but is not likely to make immediate profits, a new company is formed to take over the entire responsibility. In this way the proved industrial and the more speculative processes are separated and the possible losses on the one are not allowed to nullify the profits of the other. Two cases in point may be mentioned. One is the Mond Nickel Co., which was formed to operate Dr. Mond's nickel process. For some years this process caused considerable anxiety and worry, and the money sunk in it would have interfered with the profits of the established chemical business. These troublous days are now over, and the nickel company is making substantial profits. The other company is the Brimsdown Lead Co., which was formed to work the Bischof white lead process. This company has still to win its success. Naturally, the shares in Brunner, Mond & Co. stand at a high premium in the market. The preference shares are of £10 denomination, and their quotation today is £17. The ordinary shares are of £1 denomination, and their present price is £5. Promoters and stockbrokers are continually urging the directors of the company to increase the nominal capital in such a way as to bring the par value of the shares more nearly to the level of their market value. The directors wisely refuse to listen to the voice of the tempter, and at any rate during the life of Sir John Brunner will never adopt any such policy. Sir John does not at all like the high valuation which the market puts on the shares, holding that a far larger margin should be allowed for fluctuations in this class of business. The firm also exhibits its shrewdness in the way of handling the workmen and in devising methods of increasing their efficiency. American readers require to be told that the English law provides many stringent rules and regulations for the proper safeguarding of the health and life of the workmen. To English readers Professor Austin's recent article in the MINING AND SCIENTIFIC PRESS advocating certain decencies in the method of treating men in reduction works seems quite an anachronism, for in this country the rules that both the master and the men have to obey are all carefully thought out already. Brunner, Mond & Co. go further than these compulsory provisions. They provide gratuitous medical advice for their employees, as well as reading-rooms and clubs. They have elaborated their own sickness and accident funds. In order to keep their men, they have inaugurated a special fund by means of which they give a bonus of 6d. in the pound to all men who stay a year with them, and 1s. to those who have been with them five years. This bonus is not actually given to the men until they leave the service of the company. The firm has organized a system of holidays for the steady workmen. As a rule workmen do not get paid for their time if they absent themselves from work, but the firm was of the opinion that if holidays were regularly arranged and paid for, the men would not absent themselves so often. In 1884 the company began to give a week's holiday in this way to all men who had been a year in service and had not missed more than ten days. In that year 43% of the men qualified for their holidays. In 1907, although they had screwed up their standard from ten days lost to two days lost, they found that 97½% of the men had qualified.

Another step of no small importance taken by the firm is the encouragement given to men to stay with them as they grow old. This firm does not believe in the "too old at forty" theory. The reason for turning attention to this matter was that the firm was investigating the probable results of the new act relating to employers' liability. This act, which came into force a year ago, places upon the employer the responsibility of all accidents and illnesses met with in the course of employment, whether there is any contributory negligence on the part of the employee or not. It became necessary therefore to study the question of accidents generally much more closely than hitherto. Some firms commenced immediately to weed out old men. Brunner, Mond & Co., before doing anything rash, made investigations and found that the percentage of accidents was highest among the young men. Between the ages of 18 and 25 there are most accidents, at the rate of 8½% per annum, and this rate gradually declines until at the age of 50 or over it is less than 2½%. These figures have confirmed the policy of the directors in keeping men in the service of the company for long periods of years. It is interesting to note that Brunner, Mond & Co. have unimportant interests in mines. They have no holdings in Spanish pyrite properties, as has the United Alkali Co. A few years ago they spent large sums of money in re-opening some of the North Wales zinc mines, but found the enterprise a wild-goose chase. The only mine actually acquired was the Trelogan, and this has unfortunately not redeemed its early promise, and is now a rather irregular producer. The Mond Nickel Co., of course, owns the properties in Canada.

JOHANNESBURG, TRANSVAAL.

Metallurgical Trials Committee.—High Mill-Duty.—Output for April. —Cost-Record Lowered.—Discoveries of Molybdenum.

Some months ago the chairman of the Rand Mines Ltd., L. Reyersbach, suggested that there should be an experimental laboratory in connection with the Rand mining industry. The idea was not taken up at the time, and the various groups have continued to carry on their experimental work independently. In consequence there has been no little loss of time and money, for often one group would commence an experiment which had been proved a failure months before by some other group. There is to be a change for the better, however, for a 'Metallurgical Trials Committee' has just been formed, and in future useless duplication of experimental work will be avoided. Nearly all the mining groups are identified with the scheme. The best known metallurgical experts on the Rand are members of the committee. Every encouragement will be given to the men at the mines to bring before the committee any inventions or any proposals they may have to offer for the improvement of industrial methods.

The declaration of the gold output for April shows that the total production of the Transvaal was 565,832 oz., valued at £2,403,500, which is a decrease compared with March of 9069 oz., valued at £38,522. The amount produced by the Rand was 543,361 oz., valued at £2,308,050. Compared with March the Rand output shows a decrease of 10,079 oz., valued at £42,815. During the month there were 8875 stamps at work in the Transvaal, and of this number 8450 were crushing on the Rand. As usual there is a large variation at the different mines in the amount of rock sorted out. Two important producers, the Langlaagte Deep and the Consolidated Langlaagte mines show that no attempt was made to sort out waste rock, the run of mine being sent to the mills to be crushed. Whether this be the best policy is a debatable point. On the other hand, at some of the mines as much as 30% and over is sorted out as waste rock. There were 74 tube-mills at work in the Transvaal during the month, and this is one reason for the very satisfactory results obtained. The Luipaard's Vlei Estate again takes the lead as far as duty per stamp is concerned. At this mill the amount crushed per 24 hr. was 9.26 tons. With a 60-stamp mill this mine was able to get through 14,720 tons for April, a most creditable result. The first position for April as regards output is held by the Simmer & Jack, with an output of 25,600 oz. and a profit of £63,658. Next on the list is the Robinson mine with an output of 25,410 oz. and a profit of £80,076. Third, is the Robinson Deep with an output of 19,461 oz. and a profit of £39,052. This is certainly a remarkable trio. The Central Administration mines establish a new record in working costs for this group. The average for the eight mines works out at 17s. 3.440d. The lowest on the list is the Robinson mine, with a cost of 12s. 9.832d. per ton. This figure establishes a record for the Rand. The highest cost of the Central Administration mines for April was that of the New Modderfontein mine, namely, 22s. 6.679d. The aggregate profit for the groups for April was £868,115, which is an increase of £3411 over March. As regards labor, there is a gain in native labor figures and a loss in Chinese. Time-expired and other wastage of natives totals 9159 against 10,290 distributed to the mines, leaving a net gain of 1131 for the month. At the end of April the number of Chinese in the employ of the mines had dwindled by 2445 compared with the end of March, leaving the total indentured labor at 24,059 men.

A large deposit of molybdenum ore has been found in the Messina district. The commercial value of molybdenum is about 5s. per pound. According to the *Zoutpansberg Review*, the outcrop occurs at irregular intervals in the form of chimneys, and consists of fibrous rock resembling ironstone and quartz, strongly impregnated with crystals of molybdenum and occasional crystals of tourmaline. The existence of tourmaline and molybdenum is here generally believed to be strong evidence of the near-by existence of tin.

Witwatersrand Deep, Transvaal.

ROSSLAND, BRITISH COLUMBIA.

South-Belt Development.—Discoveries in the Josie.—B. C. Copper and Dominion Resume.

Activity in leasing and development on the prospects in Rossland camp is proving an important factor in this district. The ground is being gone over in a much more thorough manner than in the early boom days, from the fact that the local industry has come down to a conservative basis and results are what the miners are after, and not the mere staking of a piece of ground and the selling of it, as was too often the case in the early history of the camp. The work now in progress has revealed two or three excellent veins which with proper development may become producing mines, and what is more important, will prove up the mooted South Belt, which would give hope

to the many companies that own equipped mines therein. On the Josie of the Le Roi No. 2 an 8-ft. body of copper ore has been discovered that carries, at a point over 300 ft. below their present 900-ft. level, double the metal generally contained in the ore hereabouts. While the ore-bodies in the Josie have usually been narrow, though of higher grade than those in the Le Roi or Centre Star, yet there is good reason, in the opinion of local mining men, why in depth the Josie ore should not be found in larger lodes, since in both the Centre Star and the Le Roi mines gold-copper ore is found in large deposits. The Le Roi No. 2 is one of the steady dividend-producers of this district, and from present prospects will continue to distribute profits to the shareholders for some years to come, as the management is conservative and careful.

Once more the hum of wheels and the noise of industry are to be heard in the plants of the three big copper-producers of the Boundary, the B. C. Copper and the Dominion Copper companies having followed the lead of the Boundary's principal mining company, the Granby, and resumed operation at their mines and smelters. The mining and smelting men of the Boundary were placed between Scylla and Charybdis when copper dropped to such a low figure just at a time when they had overcome a multitude of other troubles. Then labor troubles were threatening, and in order to start off with a clean sheet everything was closed down. The wage difference was settled by a commission, and the outlook was that copper would recover a few cents, and with the phantom of fixed costs pressing upon them, coupled with the fact that other big producers in the United States were putting copper on the market, to say nothing of pressure from the shareholders, it was thought best to continue operation, even on the basis of trifling profits. Granby resumed early in the year, the B. C. Copper a few weeks ago, and now the Dominion Copper Co. will soon have things in running order.

While general business interests in this district will bear a rosy appearance, the managers of the mining companies will have a season of the hardest work they have ever experienced. The watchword 'economy' will have to be ever before them, for they will have to show favorable results or some good reason why they were not obtained to satisfy those concerned. Labor and money-saving devices of many sorts will have to be adopted, and every leak that can possibly be stopped attended to. The men in charge, however, are all able and experienced, and cooperate cordially in an interchange of ideas, and everyone anticipates that the Boundary miners will succeed in digging out their low-grade ore and marketing their copper in the face of the present low price of the red metal.

It has been claimed that the Granby Consolidated could make but little over expenses owing to the low price of copper, but the best answer to this assertion is found in the dividend of 2% recently declared upon the par value of the stock outstanding, payable out of the earnings of the company, on June 13. The dividend amounts to $270,000, and is the ninth one declared by the company, the total of all dividends to date amounting to $3,238,630.

MEXICO.

Revision of Mining Law.—Conference with the Chamber of Mines.

The anti-foreign articles in the proposed revision of the mining law, mentioned in my letter of last week, continue to attract the greatest attention by all concerned. The committee of the Chamber of Mines, composed of J. L. Requeña, Salvador Calcino, Rodolfo Reyes, Carlos Robles, and Ramón Alcázar, prominent in legal and mining circles in both Mexico City and Guanajuato, had an audience with the Minister of Fomento, Olegario Molina, for consideration of the anti-foreign clauses. Lic. Riqueña acknowledged the general excellence of the proposals, expressed appreciation of the adoption of many of the suggestions made by the Chamber of Mines, but stated that for the good of the country he must object to Articles 141, 142, 143, and 144. Carlos Robles showed what foreign capital had done for the country, and also called attention to the fact that ten years ago Guanajuato was practically dead, while today it was alive and vigorous under the stimulus of foreign capital, and stated that two other old abandoned camps were being investigated by foreign capitalists, but if the new provisions were enacted into law, the inflow of capital for mining ventures would cease, and as a result the mining camps would be abandoned to the country's resources, which at best were limited. Mr. Molina replied that when the Government granted concessions it imposed conditions and the solicitor accepted or refused them, and so far there had been no objection to forming Mexican companies, but with mining companies it was different. An ordinary transfer of land put them in possession, and as it was difficult to control a person or company once in possession, it was best to make the requirement that only a Mexican company should be able to acquire the ground. The Minister further expressed himself in substance to the effect that Articles 141, 142, and 143 only reproduce the law of February 1, 1856, which requires that foreigners obtain permission from the Executive to acquire land within a zone 20 leagues wide along the frontier, but extends it to include the entire area of the frontier States and Territories as regards mining properties, this being simply a precautionary measure against renegades and adventurers. Thus the Government would hold the power to prevent their obtaining land and working out fraudulent schemes. Article 144 is new to Mexican legislation, and while it is true that by liberality toward foreigners great national progress has been attained, circumstances now have changed. The outcome of the conference was that Mr. Molina agreed to present the whole matter, with the recommendations for and against the anti-foreign articles, to the Cabinet for further consideration. It is understood that Mr. Molina still adheres strongly to the arguments in favor of the adoption of the anti-foreign clauses, and will work hard for the bill. It is possible, however, that it may never go to the Mexican Congress, as it is a measure that may be acted upon by the President as an executive order without consulting the legislative body. It may be many weeks, therefore, before final decision is reached, and the general impression is that the objectionable clauses will be greatly modified or entirely cut out.

SALT LAKE, UTAH.

Revival at Park City.—Speculation in Tintic Stocks.—Majestic Copper Co.—Garfield Smelter.—Water-Right Decision.

A marked revival, due largely to the restoration of the Ontario drainage adit, has come to the Park City district. A number of mines which had been idle have resumed operation, the latest among the larger producers being the Daly-West. The mine and mill of the latter were started up again early this week. Since the beginning of the year the production of ore has been confined almost entirely to the Daly Judge and Silver King Coalition, but neither of these mines has moved a large tonnage. The latter is preparing to operate, however, upon a much larger scale. This company has recently acquired the Jupiter group, which will be added to its already extensive holdings. Last week's shipments from the Park City district amounted to 497 tons; the Daly Judge contributed 237 and the Silver King Coalition 260 tons. Outside of Bingham, Tintic is the most active mining district in the State, and from a stock-market point of view it is by far the most attractive; at least it has been during the past two weeks, when the sales on the Salt Lake Stock & Mining Exchange aggregated close to $2,000,000. The output of ore from Tintic last week was between 50 and 60 carloads, whereas twice this amount is sent out every day by one Bingham mine, the Utah Copper. However, with the starting of the new Tintic smelter, and also of the United States Smelting Co.'s lead plant at Bingham Junction, under the modified decree of the Federal Court, the situation as far as the Tintic producer is concerned will be materally improved. It will be well along in July before either of these plants will be ready. The Uncle Sam Consolidated, which has an unexpired contract with the United States smelter, but which has been out of the market entirely since last November on account of the smelting com-

pany's troubles over adverse smelter-smoke decisions, has made temporary arrangements to ship to the American Smelting & Refining Co., and will send the latter at least 2000 tons of lead-silver ores.

Advices from the East indicate that a reorganization of the Majestic Copper Co. has been effected, and the Majestic Mines Co., which is to be its successor, has been formed. The Majestic properties are in Beaver county. The Indian Queen Consolidated, also operating in Beaver county, has recently acquired 16 additional claims, giving it possession of more than 60 in all. Electric power-equipment was recently installed at this property, where a very energetic development campaign is in progress. The Garfield Smelting Co. has been experiencing much difficulty of late in taking care of the ore sent to it by customers, due partly to mechanical troubles and to the lack of adequate furnace capacity. The sampling-mill, which has never fully come up to expectations, has caused the management much annoyance, with the result that the company has had heavy demurrage expenses. It is estimated by an official of the smelting company that there is an accumulation of between 40,000 and 50,000 tons of ore in the smelter yards at this time. While the May output of the Consolidated Mercur mine is not yet definitely known, the management asserts that it will exceed that of April, which was approximately $65,000. The mill is treating about 800 tons of ore per day. The Sunshine mine, in the Mercur district, is to be started again soon, at least as soon as necessary alterations are made in the mill. The Sunshine property was bought over a year ago, under an execution, by officials of the Consolidated Mercur, who will adopt more modern mill-methods. The Gold Mountain Consolidated Mining Co., owner of the Annie Laurie mine at Kimberly, Utah, has been experiencing some financial troubles. Application may be made for the appointment of a receiver. The Ontario Silver Mining Co., at Park City, has been given a decision in the Federal Court in a case involving the right to water from the Ontario drain adit. The Wasatch Irrigation Co. claimed that the adit tapped the flow of water from certain springs which were their source of irrigation, and consequently the irrigation company had the right to use the water after it came out of the tunnel. This view, however, was not taken by Judge John Marshall in arriving at his conclusion. Reference is made by him to the fact that the Ontario owns a considerable portion of the land underlying the drained territory, and had holdings in the lands above the mine proper. Other parts affected by the drainage was public domain, hence the irrigation concern had no rights or privileges pertaining thereto.

RENO, NEVADA.

Dedication of Mining Building of the State University. — Mackay Benefactions.

Last week was one of momentous interest to all friends of the University of Nevada, and those who have followed the history of the institution firmly believe that it also marks the beginning of an epoch of increased prosperity and greater usefulness. With the regular graduation exercises of the class of 1908 were combined the dedication of the new mining building and the unveiling of a statue of John W. Mackay. Both the building and the statue are the gifts of Clarence H. Mackay and his mother, the son and wife, respectively, of the famous pioneer of the Comstock. The new home of the Mackay School of Mines is a two-story brick building of simple architecture, done in red brick with a black border, and trimmed with Indiana limestone. The first floor is devoted to the metallurgical, assaying, and chemical laboratories; the geological museum, library, and lecture-room; the research laboratory; and the weighing and acid rooms. The second floor contains the mineralogical laboratory, the mining lecture room, offices, store rooms, and the like. The building is the design of McKim, Mead & White, of New York. The building cost $75,000, and the furnishings $12,000. The statue of John W. Mackay is of bronze, and stands directly in front of the new building. It represents a miner with his flannel shirt open at the neck, his sleeves rolled up, carrying a pick in one hand, and apparently just 'up from below.' It is the work of Gutzon H. Borglum, himself a native of Utah, but trained in the Parisian studios of Rebisso and Frémiet. Mr. Clarence Mackay and his wife were present at the exercises during the week, and entered enthusiastically into all functions, both social and academic. Nor are these gifts all Mr. Mackay has done for the University. He has agreed to furnish an endowment fund, from the proceeds of which the salaries of the instructors in the School of Mines shall be paid. He has furnished the money for beautifying the campus, according to plans prepared by McKim, Mead & White, and by Bliss & Faville, of San Francisco, and he has

Mackay Mining Building, University of Nevada.

contributed liberally to the athletic fund of the student body. It seems especially appropriate that wealth which was drawn from the mines of the State should now be turned toward its only institution of higher learning. Mr. Mackay and his mother are to be congratulated on the spirit which prompted these benefactions. However, the people of Nevada should not lose sight of the fact that the institution of learning on the hill above Reno is a State institution, and that it is dependent upon the State of Nevada for its support and development. The School of Mines will probably always be its largest and most important department, but the others are essential to it, and to the growth of the State at large. The last session of the Legislature demonstrated that Nevada has realized, in part at least, its responsibility, and that it will stand behind the University of Nevada and the men who are devoting their time and strength to its work. No reference to the prosperity and growth of the University of Nevada would be complete without the mention of the man who has given so much of his personality and vitality to it. Joseph Edward Stubb's name will be prominently linked with its history, as will the name of George J. Young with the School of Mines, whose moving spirit he has been for many years.

BUTTE, MONTANA.

Net Earnings of Butte Companies.—Reports to County Assessor.

The principal copper producing companies of the Butte district have made their annual reports to the county assessor, showing operating expenses, gross earnings, and net proceeds during the year ending June 1, 1908. These reports are made annually for the purpose of taxation on the net earnings. Ten companies, the Boston & Montana, Anaconda, Butte & Boston, Washoe, Parrot, Trenton, Alice, North Butte, Butte Coalition, and Original, which comprise practically all of those that made a profit, show net earnings of only $4,648,261.44, against $20,263,291.81 for the year ending June 1, 1907, a decrease of $15,615,030.37. All of the Amalgamated, North Butte, and Butte Coalition (Red Metal) mines operated at full capacity for only about three months during 1907. For three months more they operated only to the extent of 35% of normal capacity, and for three months more were all, with the exception of the Boston & Montana mines, closed entirely. For the first time in many years the Parrot company shows a loss in operation, while the Washoe Copper Co. enters the list of profit-earners with $246,096 net. In previous years the Washoe earnings were more than absorbed by expenditures for construction and improvements.

The net proceeds reported for this year, compared with those of last year, are as follows:

	1908.	1907.
Boston & Montana	$1,561,065	$7,049,988
Anaconda	1,132,875	5,819,184
North Butte	1,113,647	3,271,213
Butte Coalition	71,810	1,432,760
Butte & Boston	295,604	1,249,467
Trenton	67,259	481,623
Parrot	.....	141,730
Washoe	246,096	.....
Original	159,902	663,259
Totals	$4,648,261	$20,263,291

The tonnages of ore extracted were: Boston & Montana, 967,685; Anaconda, 824,420; North Butte, 284,003; Coalition, 243,960; Trenton, 85,260; Butte & Boston, 193,830; Parrot, 57,964; Washoe, 115,620; Original, 245,853; Alice, 1500. The gross yield per ton was: Boston & Montana, $10.10; Anaconda, $9.11; North Butte, $11.36; Butte Coalition, $8.53; Trenton, $7.58; Butte & Boston, $8.31; Parrot, $7.70; Washoe, $9.11; Original, $8.20; Alice, $8.21. Cost per ton for extracting: Boston & Montana, $4.04; Anaconda, $3.96; North Butte, $3.49; Butte Coalition, $4.39; Trenton, $3.57; Butte & Boston, $3.30; Parrot, $6.57; Washoe, $4.21; Original, $4.60; Alice, $10.72. Cost of transportation: Boston & Montana, $733,352; Anaconda, $101,455; North Butte, $55,305; Butte Coalition, $53,628; Trenton, $10,318; Butte & Boston, $39,472; Parrot, $8125; Washoe, $221,881; Original, $54,766. Cost of reduction per ton: Boston & Montana, $3.06; Anaconda, $2.70; North Butte, $3.75; Butte Coalition, $3.63; Trenton, $2.39; Butte & Boston, $2.29; Parrot, $2.70; Washoe, $1.92; Original, $2.72. Paid for labor: Boston & Montana, $3,029,273; Anaconda, $2,641,282; North Butte, $990,405; Butte Coalition, $1,070,272; Trenton, $255,489; Butte & Boston, $511,711; Parrot, $240,333; Washoe, $416,-511; Original, $774,560. (In the items of cost of the North Butte and Coalition are included all mining costs.) Cost of marketing copper, including seaboard charges, refining, and selling: Boston & Montana, $617,513; Anaconda, $788,998; Trenton, $60,700; Butte & Boston, $191,385; Parrot, $51,714; Washoe, $83,108; Original, not reported. Other companies have no item of this cost, as they sell to local smelters. Paid for machinery and supplies: Boston & Montana, $3,833,-913; Anaconda, $2,846,868; North Butte, not reported; Butte Coalition, not reported; Trenton, $252,314; Butte & Boston, $571,688; Parrot, $296,676; Washoe, $292,638; Original, $356,-678. Freight on ore: Boston & Montana, $733,352; Anaconda, $101,455; North Butte, $55,305; Butte Coalition, $53,628; Trenton, $10,318; Butte & Boston, $39,472; Parrot, $8125; Washoe, $14,602; Original, $54,766. Gross proceeds: Boston & Montana, $9,775,118; Anaconda, $7,511,479; North Butte, $3,224,763; Butte Coalition, $2,080,249; Trenton, $646,-109; Butte & Boston, $1,609,763; Parrot, $457,479; Washoe, $1,052,956; Original, $1,915,994; Alice, $12,318. Total cost of production: Boston & Montana, $8,214,053; Anaconda, $6,378,604; North Butte, $2,111,115; Butte Coalition, $2,008,-438; Trenton, $578,849; Butte & Boston, $1,314,158; Parrot, $596,851; Washoe, $806,860; Original, $1,756,092; Alice, $16,085.

CRIPPLE CREEK, COLORADO.

Blue Flag Mill.—Prince Albert Development.—Shipments Improving.—Friday Leasing Co.—Iowa Girl.

The Blue Flag, at Breckenridge, has suspended operations for a period of two months. Some of the machinery in the mill recently gave out, and the cessation of operation was originally made to allow time for repairs. Now the management has decided to completely re-equip the plant with new machinery. To that end, additional electric appliances, drills, and minor equipment will be purchased. The Prince Albert Gold Mining Co., which owns a large block of land on the southeast slope of Beacon hill, at Cripple Creek, has decided to abandon the leasing system and work the property on company account. An adit will be driven, starting in the gulch which separates Grouse from Beacon hill, to strike the Prince Albert vein at a vertical depth of 600 ft. The vein is exposed for a distance of 1200 ft., and the assays average about $8 to $10. The pay-roll of the Cripple Creek district for last month is estimated to be almost $350,000. The camp is in a prosperous condition, and the volume of shipments is the largest ever known in the history of the camp. One of the gratifying features of the present output is the fact that, along with the great quantity of low-grade ore being sent out, there is also a large amount of high-grade, so that the bullion value is kept up to the level of early days.

The Friday Leasing Co., operating on the Friday claim of the White City Gold Mining Co., on Tenderfoot hill, is doing an immense amount of development work on the first or 80-ft. level in a new shaft which has been sunk during the past six months. Cross-cuts have been extended to the north side-line and another is now being run east from the shaft. Several veins have been cut recently and development work is in progress the greater portion of the time. The veins show low-grade ore and no attempt is as yet being made to ship any of it. The ore is being blocked out, and it is the intention of the management of the leasing company eventually to erect a large cyanide mill, which may be started toward the latter part of the present year. The Friday Leasing Co., which is composed chiefly of Denver men, has a bond on the property in the sum of $200,000, with a long-time lease.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Rubber belts or gaskets may be cut much easier if the knife is wet with water, or better still with a strong solution of potash. The purer the rubber the more difficult is it to cut without wetting.

Fire damp, in America, is usually understood to mean any explosive mixture of marsh-gas and air. In England, however, the term is often applied to any mixture of gas and air, whether explosive or not.

Gravel in place is usually estimated at 3000 lb. per cubic yard, and the standard sheet iron pan, 16 in. diam. at top and 10¾ in. diam. at bottom, will hold 20 lb., hence 150 pans-full will make a cubic yard of dirt.

Thawing dynamite in hot water is poor practice, aside from the inherent danger of the method, since the nitroglycerine leaks out of the dynamite into the water and its presence is not suspected, or is forgotten, until an explosion results.

Available horse-power in a water-fall may be determined by the formula: hp.=0.1134 Hqe, in which H is the effective head, in feet, above the wheel; q the quantity of water in cubic feet per second; and e the efficiency of the wheel.

Graphite, when added to oil, increases its lubricating qualities, decreases the amount required, and allows the use of a lighter or poorer quality of oil. It is claimed that even a mixture of water and graphite may, under favorable conditions, serve as a satisfactory lubricant.

Timber superior in strength and in resistance to decay is usually found on dry, sandy, or rocky soil, on hill-sides or in relatively open forests on rolling ground, and that standing near the edges of woodlands will be found better than that from the interior of dense growths.

Transmission of power by compressed air was first proposed and tried by Denis Papin, in 1653. He proposed to use air, confined in a pipe, as a long piston transferring work to a distance. He also first conceived the idea of a pneumatic tube for transmitting parcels by air-pressure.

Specific gravity of liquids, referred to water as unity, may be calculated from the reading of the Beaumé hygrometer-scale by adding 133 to the observed degree, and dividing the sum into 143. For example, linseed oil registers 20° B. Therefore $\frac{143}{133-20}$=0.934, the actual specific gravity.

Boiler-feed water should contain no more than 5 parts in 100,000 of either sulphuric or nitric acid, otherwise serious corrosion will result. Neutralization of acid mine-waters, which always contain H_2SO_4, may not be accomplished with lime. A large part of the calcium sulphate formed remains in solution, and deposits as a particularly hard and insoluble scale in the boiler. Neutralization with soda ash, the commercial carbonate of soda, is the only safe method. This is prohibitive on account of the cost in most parts of the western United States.

Current velocity of from 2 to 3 ft. per second is ordinarily sufficient to prevent the growth of weeds or the deposition of silt in canals. The banks of a canal in firm sandy loam will not erode with a velocity of 3 to 3½ ft. per second, and in gravel or hardpan the velocity may be increased to 5 or 7 ft. per second.

Stencils may be made by cutting the desired outline or lettering out of heavy paper, and with it stencil the design on a thin sheet of zinc, using dilute hydrochloric acid for a paint. Better results will be obtained if the paper stencil is glued tightly to the zinc before the acid is applied. When the zinc has been corroded, file the edges smooth.

Amortization is the provision of a fund, made from earnings, independent of dividends, which will, in a given period, repay the original investment. A mining enterprise, in the great majority of cases, is terminable, not permanent, and should therefore return not only ordinary interest on the capital, but a further sum sufficient to repay the original capital during the life of the mine. The fairest and most systematic method of accumulating such a fund seems to be in the form of a fixed charge on the ore mined, based either upon quantity or upon the value, according to the nature of the mine.

Phosphor-bronze is a term used to define an alloy of copper, tin, and phosphorus, with or without lead. The phosphorus is placed in a perforated bell-shaped receptacle made of graphite, with a long handle. This is thrust into the molten copper. Violent ebullition occurs. From 20 to 30% of the phosphorus burns, the rest alloying with the copper. The tin is then introduced. Phosphor-bronze contains from 90 to 95% copper, 9 to 4.5% tin, and from 1 to 0.5% phosphorus. For bearings a good phosphor-bronze alloy is: copper 80, lead 10, tin 8, and 2% of a 5% phosphor-tin alloy.

Flow of water in a pipe was recently stated in this column, to be proportional to the square root of the fifth power of its diameter. Several correspondents have objected to this, and it has been advanced that the discharge varies as the square of the diameter. Our statement was based upon a formula which is an attempt to include, in a simple form, all the factors governing the flow of water in long pipes, and is, of course, only approximately true. Areas of circles vary directly as the square of the ratio of their diameters, but the discharges from straight long pipes of uniform cross section are dependent not only upon the area, but upon the length, the roughness of the interior surface, and the velocity. Vallot, a French engineer, has proposed a formula in which the discharge varies as the cube root of the eighth power of the diameter. This is closer to the truth than the square root of the fifth power, as stated by us.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Cyanidation in Nevada.

The Editor:

Sir—Since the appearance of Mr. Lochiel King's article in your issue of January 25, I have had an opportunity of making actual mill-runs on about 700 tons of the sulphide ores taken from the lower levels of the Combination and Mohawk mines, at Goldfield. This was selected as representative of the lower-level sulphide ores, and represented an average of what the new mill of the Goldfield Consolidated would have to treat for a long time. It consisted of a mixture of hard and soft talcose ore, the hard portions showing the sulphides very finely and evenly disseminated throughout the matrix.

This material was treated by our usual methods at the Combination mill, which was originally designed to treat oxidized ore. The results are summarized thus:

	Tons.	Gold, oz.	Per-centage.
Wet ore	506.57	.....	.....
Moisture	.....	.....	5.8
Dry ore	477.19	.....	.....
Crushed per stamp-hour	0.26	.....	.....
Average assay	.....	1.77	.....
Total gold contained	.....	844.62	.....
" recovery by amalgamation	.....	226.54	.....
Extraction by amalgamation	.....	.....	26.82
Sand concentrated	117.10	.....	.....
Concentrate produced	10.01	.....	.....
Assay of concentrate per ton	.....	14 01	.....
Slime concentrated	360.75	.....	.....
Concentrate produced	8.37	.....	.....
Assay of concentrate	.....	16.54	.....
Total gold recovered by concentration	.....	279.00	.....
Extraction by concentration	.....	.....	33.04
Sand leached by cyanide	107.29	.....	.....
Assay of sand heading	.....	0.797	.....
" " tailing	.....	0.104	.....
Extraction from sand by leaching	.....	.....	86 90
Slime treated by agitation	351.70	.....	.....
Assay of slime heading	.....	0.72	.....
" " " tailing	.....	0.13	.....
Extraction from slime	.....	.....	80 93
Total extraction by cyanidation	.....	.....	32.91
" " " amalgamation, concentration, and cyanidation	.....	.....	92.77

The stamps weigh 1200 lb. apiece, they drop 5½ in. at the rate of 108 drops per minute, and the discharge is through Tyler double-crimped 16-mesh 22-gauge wire-screen.

The average time of leaching with weak solution was 9 days; with strong solution, 5 days; so that the total time was 14 days. The weak solution contained 0.8 lb. KCy per ton and the strong 3 lb. per ton. The consumption of KCy was 1.08 lb. per ton of ore treated.

The average time of agitation was 14 hours and the strength of cyanide solution 1.5 lb. per ton; the consumption of cyanide being 1.2 lb. per ton of ore. All samples were taken at 15-ft. intervals throughout the test, at the head and tail of each step in the process, and careful screen-tests were made of all the samples and each size assayed, showing where the gold lay, before and after treatment by each process. I give a battery-discharge screen-test, so that some idea may be gained of the physical nature of the ore.

Mesh.	%
Held on 40	9.9
" " 60	14.0
" " 80	5.6
" " 100	7.9
" " 150	3.6
" " 200	1.2
Passed 200 (sand)	2.7*
" 200 (slime)	51.9*

* Determined by a rising current of water.

This test showed plainly what could be done with the inadequate facilities at the Combination mill, and also indicated what could be expected from a properly equipped plant, to treat the ore by the method outlined in the test. It is apparent that, physically, the ore lends itself readily to wet-crushing. When carrying 5.8% moisture, 57.6% passes 200 mesh when stamped through a 16-mesh screen at the battery. This shows the soft nature of the ore. Both of the conditions are inimical to dry-crushing in ball-mills, the moisture and soft material making it necessary to dry the ore, and the amount of soft material present retarding the grinding effect of the mills on the harder material. The stamp-duty is shown to be large, and the mechanical results justify the stamps. By amalgamation, a recovery of 26.82% was made, as against 4.2% shown by Mr. King, and this could have been materially improved had our plate-area been larger. A saving of 33.04% was made by concentration, this being represented by 18.4 tons of concentrate, or 3.85% of the total ore treated. It was shown that practically no extraction had occurred on the material held on a 40-mesh screen, by either amalgamation or concentration, and but 45% extraction on such material as remains on 80-mesh. It was demonstrated that all material should be ground sufficiently fine to pass 100, or 150, mesh to obtain the best results. By such fine-grinding a large increase in the gold saved by amalgamation is obtained, by reason of which the concentrate will have a much lower value, and a larger portion of the sulphide will be liberated, allowing better concentration, with a residue more free from sulphide for cyanidation. This calls for large plate-area and proper concentrating facilities, neither of which were available during the test.

In the treatment by cyanide, the same conditions affected the extraction, that is, sand coarser than 100-mesh, and fine sulphide slime, due to poor concentration. The sand finer than 80-mesh and coarser than 200-mesh represented 47.7% of the product leached, and on this product the extraction was 97.36% of the original gold content of the ore. This product between —80 and +200 mesh was such that the proper comminution for the best extraction had been reached and the free gold and sulphide liberated, allowing of the best amalgamation and concentration, and there is no reason why as good results should not be obtained on the product coarser than 80-mesh if ground sufficiently fine.

The following is a screen-test on the sand-tailing after leaching:

Mesh.	%	Gold, oz.
Held on 40	0.1	0.19
" " 60	8.8	0.14
" " 80	10.5	0.11
" " 100	20.5	0.04
" " 150	24.0	0.05
" " 200	3.2	0.05
Passed 200	32.5	0.114

Screen-test on slime treated by agitation:

Mesh.	%	Gold, oz.
Held on 100	1.4	0.06
" " 150	3.3	0.08
" " 200	1 1	0.08
Passed 200 (sand)	3.9	0.16
" 200 (slime)	90.1	0.18

On the material coarser than 200 mesh in this agitated product, an extraction of 95.77% was made from the original content of the ore, at the end of

14 hours' agitation and filter treatment. Several agitator-charges were sampled each hour during agitation, to determine the rate of solubility of the gold and the time necessary for agitation; the following is an average of results of such sampling:

Time of agitation. Hours.	Assay of pulp. Oz. gold per ton.
1	0.73
3	0.43
6	0.34
9	0.30
12	0.26
14	0.30
Extraction during agitation	58.9%

These special charges were sent to the storage-vats; the filter-charges made and treated separately. After the cake was formed the gold-bearing solution was displaced with a waste solution, carrying 0.4 lb. KCy and 6 cents gold per ton. The washing was continued with this solution for 45 minutes, with the following results:

Charge going to filter-box	0.30 oz. gold per ton
After 45 minutes washing	0.132 " " " "

Extraction in the filter-box was 23%, bringing total cyanide extraction on slime to 81.9%. While the results of the screen-tests showed what can be done with the material coarser than 200 mesh, it still leaves us with 76.78% of the total material stamped on which only 90.8% extraction has been made, but by careful concentration the same can be brought up 3.7%, making 94.5% extraction on this product with proper equipment. The deductions to be made, after considering the treatment of the ore by this method, to get the best results, are:

1. The ore to be stamped through as coarse a screen as possible to allow such material as readily forms slime, when crushed with water, to discharge as quickly as possible, and avoid sliming the harder particles. The battery-pulp to flow to classifiers for the separation of such slime and sand finer than 100 or 150 mesh; the coarser product going to the tube-mills. The total plate-area for amalgamation should be double the area ordinarily used, so as to allow of decreasing the velocity of the flow of the pulp over the plates to such a degree that the now fine sulphides will not unduly lag and retard amalgamation. Such area will also allow of some dilution (if the water applied in classification is not sufficient) to decrease the density, for, while the water may be ample for good amalgamation, as ordinarily discharged with the pulp through a 20-mesh screen, such is not the case after all the pulp has been ground to pass 150 mesh. It will then carry a large amount of fine gold in suspension unless very dilute.

2. Ample concentrating facilities should be provided, which in this case also means area, and not an intricate system of classification, for we are dealing with fine sand and slime and the concentration does not have to cover a wide range of material. With our ores the slimed sulphide does not rapidly oxidize and become suspended on the surface of the water, as is often the case with the sulphides of silver, lead, and copper.

3. Large settling area should be provided, to allow of settling the slime and de-watering to the fullest extent, so that all reducing action by the water, in which the ore has been treated up to this point, may be removed. The agitator capacity to be such that after three or four hours' agitation the pulp may be allowed to settle and the supernatant liquor decanted for precipitation and the agitation again commenced with a precipitated solution. These decantations and changes of solution to be made as many times as may be found necessary.

Such a method of procedure is made necessary by the rapid reducing-action of the ore, as shown by the figures given in the agitation test mentioned (and many others that I have made). The gold goes rapidly into solution during the first hour of treatment, and then more slowly until finally it ceases entirely at the sixth hour of agitation, negative results being obtained for the remaining eight hours of agitation. It was also shown that upon removing the solution in which the slime was agitated and washing with a precipitated solution carrying 0.4 lb. KCy per ton, the gold was dissolved almost as rapidly as during the first hour of agitation.

From the large number of experiments made along the lines of the mill-run mentioned, I have no doubt but 95 to 97% extraction can be made on these ores of a $50 value. Hence (but for the approximated 6% of concentrate, that we have on hand, still to be treated) our extractions are such that if commercially equal then the roasting of the crude ore need not be considered. And the fact being that roasting gives good results by cyanide on the roasted crude ore, the same will also hold good in the case of the concentrate that can be roasted and treated at the mill at a cost not to exceed that of treating the crude ore. The fuel consumption should be less when considering the amount of sulphur contained, as shown by analysis.

ANALYSIS OF CONCENTRATE.

	%		%
Sulphur	41.5	Lime	Trace
Iron	35.9	Magnesium	"
Copper	0.64	Alumina	2.68
Lead	Trace	Gold	0.04
Tellurium and selenium	0.25	Silver	0 01
Bismuth	0.12	Arsenic	Trace
Zinc	0 19	Antimony	0.10
Manganese	0.04	Insoluble	18.30

In the matter of cost of operation of the two methods, for comparison, I give the following data in cents per ton of ore, on a basis of 600 tons per day by the wet method of stamping, amalgamating, and concentrating, as against drying, crushing, and roasting.

Cost of stamping.—Power			$0.12
	Supplies and repairs		0.10
	Labor		0.0616
	Total		$0.2816
Amalgamation.—Supplies			$0.03
	Refining		0.011
	Labor		0.10
	Total		$0.141
Concentration.—Power			$0.022
	Supplies		0.0165
	Labor		0 0388
	Total		$0.0773
Tube-Milling.—(5 mills, each 5 by 22 ft.) 248 tons of sand.			
	Power	$0.10	(2.1 lb. pebbles per ton)
	Supplies and repairs	0.062	(4 in. silex lining once per year.)
	Labor	0.026	
	Total	$0.188	
	Equaling	0.0777	per ton stamped.

Roasting.—36 tons of concentrate at $1.25 per ton equals 7.5 cents per ton stamped.

These labor items include the services of a repair crew of four men, aside from the regular attendants.

Total cost (not including primary breaking) of preparing the ore for cyanidation is 65.26 cents per ton.

On the other hand, the cost of crushing crude ore in 'Kominuters' and roasting 600 tons per day is:

Operating 3 Kominuters.—Power		$0.0666
	Steel balls	0.0682
	Labor	0 0200
	Total	$0.1548
No data on screen and weight of liners.		
Drying the ore.—(Six 100-ton drying furnaces)		
	Power	$0.0533
	Repairs	0.03
	Fuel	0.055
	Labor	0.02
	Total	$0.1583
Roasting.—$1.25.		
Tube-milling.—(480 tons) $0.1501.		

Total cost (not including primary breaking) of preparing the ore for cyanidation is $1.7135 per ton. No account is taken here of operation and maintenance of conveying and cooling apparatus, dust-chambers, feeders, and storage. No labor is added to the repair items.

The operating cost for drying, comminuting, roasting, and tube-milling is seen to be $1.7135. For stamping, amalgamating, concentrating, and tube-milling, $0.6526. A balance in favor of the latter method of $1.0609.

When considering construction costs, there is no doubt but 100 stamps will greatly exceed the cost of three Kominuters; at the factory they only represent a small portion of the costs of the total necessary equipment in place, to complete the part of the process covered. For we have drying furnaces, Kominuters, roasting furnaces, coolers, storage-bins for feed to roasters and also tube-mills, conveyors, motor equipment of 700 hp., besides dust-chamber and stack. From the fact that the ore has been dried, twice the quantity will have to be tube-milled, making that item of installation double.

At the Golden Cycle mill, in Colorado, the dust-chamber, as nearly as I can remember, is 16 by 16 by 300 ft., with a 125-ft. concrete stack for eight Edwards furnaces. If this is necessary with the $8 to $10 Cripple Creek ores, it certainly would be with Goldfield ores assaying $50 per ton.

Against this we have 100 stamps of 1050 lb. apiece, 40 sets of amalgamating plates, 80 concentrators, five 5 by 22 ft. tube-mills, one 36-ton roasting-furnace, with dust-chamber, stack, and cooler, and finally a motor equipment of 625 horse-power.

I have confined myself to a comparison of the apparatus; not having the cost and shipping weights of the roasting machinery, hence I cannot compare the two systems by actual cost, but think that it will be found in favor of the wet-crushing method. I fully agree with Mr. King, that the gold saved by amalgamation, when fine-grinding is resorted to, could also be recovered by the subsequent cyanide treatment, without the added expense, but I am a firm believer in the millman's motto: "Get your gold as soon as you can," and there are good reasons for doing so. By estimating our ore at $50, and by making 28% extraction by amalgamation on 600 tons per day, we have $8400 daily, already in the form of bullion. The chances of a material loss are greater the longer the gold stays in the plant, and the farther it is carried, especially when it is being carried by solution. There is some small loss each time it is handled, either in the form of solution or precipitate. If simple amalgamation will decrease the value of your solutions by three or four dollars per ton, in addition to the other advantages mentioned, I think the additional expense is warranted.

As to concentration, I do not see any difficulty when concentrating after tube-milling, as one treatment serves the purpose, without the series of concentration and reductions mentioned by Mr. King. When crushing to 40 mesh such a series of concentrations and reductions would be necessary, as we have shown that practically 150 mesh is the liberation point of the free gold and sulphide. The 8% of concentrate mentioned by Mr. King probably contained a large amount of free gold, and sulphides in particles of gangue, which made the percentage of concentrate and values so high. The re-grinding of the 40-mesh sand again liberated an appreciable amount of fine sulphide, which made the series of concentrations seem necessary. Such series of reductions undoubtedly seem entirely proper to anyone treating concentrating ores, where in most cases (the value of the ore permitting) comminution and concentration by stages is the only proper treatment to avoid heavy losses by sliming. Looked at from a concentration standpoint, my suggestion, of amalgamation and concentration after tube-milling, may seem the height of folly. But to illustrate to what degree these fine sulphides can be concentrated, even with the inadequate facilities during the test, I attach the following screen-test on the concentrate produced during the mill-test mentioned:

From Sand.			From Slime.		
Mesh.	%.	Oz. gold.	Mesh.	%.	Oz. gold.
Held on 40	0.95	.....			
" " 60	0.57	15.06			
" " 80	1 05	.....			
" " 100	3.90	17.90	Held on 100	0.43	43.62
" " 150	14.25	13.18	" " 150	1.77	11.60
" " 200	13.70	12.20	" " 200	3.96	10.76
Passed 200	65.57	13.36	Passed 200	93.84	15.64

By fine-grinding and proper amalgamation, a large amount of fine gold is obtained that would otherwise be carried into the concentrate, largely increasing its value, which does not improve conditions even if it is expected to be treated on the ground, for reasons already explained, that is, the gold has to go through two or three more stages of treatment with a possibility of further loss. And as Mr. King has already explained, in the event of their being shipped to the smelter, only $19.50 is obtained for considerable gold that should have been recovered by amalgamation, sent to the Mint, and settled for at $20.67 per ounce.

The grinding to 150 mesh is also sufficient to insure the maximum liberation of the sulphides; with these ores, a better concentration can be made than would be the case if contending with a wider range of sizes of material. Treating these sulphides on the ground also removes the charge of $4.25 against $50 ore, and I think that by removing them by concentration and treating them separately, a much better extraction can be made than if they were roasted and treated with the ore. For changes in treatment can be made to suit the conditions for 36 tons of rich material that would be prohibitive when treating the whole 600 tons of crude ore, and I do not think that there can be any question that the roasted sulphides assaying $398 per ton (as per Mr. King's test) would demand

some different treatment to suit the conditions and obtain the best results, other than that given the roasted gangue. By assuming an extraction of 97.6% on such material, it will still leave $11.70 per ton in the tailing, which does not appear to be much when expressed as 2.4% loss, but appears very different when expressed as $11.70 per ton for 36 tons per day.

Before dismissing the comparison of cost and extraction, I think it well to call attention to the fact that we have been dealing with a quantity of 600 tons per day (the estimated capacity of the Consolidated new mill) at a value of $50 per ton. It is reasonably well known that a mine that produces $50 ore also produces a larger quantity of $5 ore, especially where the lode-channel is as wide and broken up as that of the Goldfield district. I might add as an indicator of what is expected to be done in the way of treatment, that the division line between 'waste dump' and 'suspense dump' of the Goldfield Consolidated Co. is about $4. The item that fixes the value of the ore to be treated is cost of mining + cost of milling + the amount of profit demanded. So we shall "come down to earth" and make a comparison on a conservative average between high-grade and low-grade, and say $15 per ton; then a difference of 8.5% extraction is equal to $1.27 per ton.

Should the cost of roasting be the only addition, I think we are very close to the margin of economy, allowing that the roasting method will give the better extraction by 8.7%—something that it cannot do. The actual difference in the best results obtained by roasting and the mill-test given is 4.8%, which equals 72c. per ton on $15, and the difference in cost between stamping, amalgamating, and concentrating on the one hand and the comminuting and roasting on the other, as I see it, is $1.19 per ton, equaling 47c. per ton in favor of the former method, without considering that much better results can be obtained, with a mill properly equipped for this method of treatment, or that the extraction obtained by roasting was on ore assaying $58.29 per ton, while those obtained in the mill-test was on ore assaying $36.50.

If, as Mr. King has reason to believe, the greater part of the gold in the low-grade sulphide ore is present as a telluride, I must say that it is remarkably docile to treatment by amalgamation and cyanide. Thus, 220 tons of the sulphide ore, of an assay value of $24.80, were treated by amalgamation and cyanide, without concentration, and gave extraction by amalgamation of 26.27 and 47.33% by cyanidation, making a total of 73.6%. This does not bear out such a supposition. And judging from the analysis of the concentrates and various tests that have been made, I should say that a very small proportion of the gold is present in the ore as a telluride. Referring to the agitation tests in Mr. King's article, where "the results were so poor that further efforts along that line were abandoned." I can say that while I do not think economical results would have been obtained without concentration, I do think that with two or three changes of solution during agitation, the results would have called for further investigation before abandonment, as the amount of H_2S evolved during agitation rapidly consumes all the free oxygen in solution, and any further extraction ceases.

Looking upon the extraction of gold from ore by cyanidation as an electrolytic process, it will be understood that the lack of oxygen to combine with the hydrogen soon causes a polarization of the solutions; in other words, giving a weak current in the wrong direction, either suspending any further extraction of the gold from the ore, or as the polarization becomes greater, precipitating gold from the solution. This reducing condition is very pronounced with the sulphide ores of this district, and mechanical means of applying oxygen is either only slightly effected, or not at all. After the first supply of oxygen (carried in by the first solution) has been exhausted, the gold goes into solution very slowly, or only as fast as the solutions absorb oxygen to combine with the hydrogen in the solutions and keep the electro-motive force in the right direction. And where long periods of time are necessary for good extraction with these ores, the time is simply the measurement of the combining rate of oxygen with the solutions and has nothing to do with the solubility of the gold. Such gold as is soluble in the cyanide solutions in the ore will go into solution at a uniform rate until exhausted, the solution being maintained in the proper condition, and the fact that the rate of extraction gets slower and slower and covers a long period of time, does not mean that the gold is less soluble, but that the current is becoming more feeble, due to polarization. I find that the quickest way to remedy this condition is to remove such inert solution, and pass the same through the zinc-boxes. This has the same effect in the short space of time it takes the solution to go through the zinc-boxes, as a great many hours of agitation with all the aeration that can be given. In short, it is easier and simpler to remove the H_2S from the solution by precipitation than to furnish oxygen for the charge to neutralize it. Hence my reason for saying that the agitation-capacity should be such as to allow of this procedure with the Goldfield ores.

Were the ores of a hard quartzose nature, making a larger proportion of sand than slime, which would allow of easy access to the solutions throughout the cake in filter-pressing, the proper treatment would be to use the Merrill system and avoid agitation entirely. By it the water or solution (in which the ore has been crushed and which has been subjected to all the reducing actions of the ore) can be removed, and the highest efficiency of the oxygen can be obtained by blowing air under pressure through the charge, facilitating the combination of it with the hydrogen. A regulation of the flow of solution through the charge at the best rate of flow, commensurate with the best results must be made and as much solution as required can be passed through the charge.

To summarize: It is my opinion that there is no Goldfield ore, so far developed, that cannot be reduced more economically by the wet method, treating and roasting the concentrate on the ground, than by roasting and cyaniding the crude ore.

A. G. Kirby.

Goldfield, Nevada, June 2.

GOLDFIELD, NEVADA.—V.

Metallurgical Development.

Written for the MINING AND SCIENTIFIC PRESS
By T. A. RICKARD.

The metallurgist waits on the miner. Until the ore is produced, the mill cannot be supplied. At Goldfield there is a good foundation for an interesting metallurgical practice because a large tonnage of rich ore is available. Already smelting, stamp-milling, cyanidation, and chlorination have been applied successfully.

No process of treatment can be used intelligently until the character of the ore is understood. The Goldfield ore posseses three dominant features: (1) high gold content, (2) the presence of tellurides as well as free gold, and (3) alunite. Owing to its richness, it has been possible to transport the product of this district to distant smelters, at Salt Lake, Denver, and San Francisco, where it forms the silicious part of a charge fed into a blast-furnace. Lead is usually the collecting medium for the precious metals, but copper is also used; although high-grade ore is rarely smelted in the copper furnaces. To the metallurgist in charge of the smelter the Goldfield ore is just so much silica needed to combine with his iron and lime in order to form a slag of suitable fusibility. The richness of the ore affects the sampling more than the actual smelting. Great care is required to obtain a true sample, and it is found necessary to pass a large proportion of a shipment through breakers and rolls before obtaining the fractional portion that is assayed. The alumina in the Goldfield ore retards the fusibility of the slag; usually there is about 7% alumina in the smelting mixture. But, on the whole, the commercial drawback to handling such rich ore is more serious than any technical difficulty; a carload of 40 tons containing $12,000 worth of gold represents a good deal of money, and it makes a great difference as to when the payment is made. The miner wants his money right away; the smelter would like to postpone payment until he gets his check from the refinery or the mint; between the date of shipment from the mine and the date when the gold and silver in the ore are available as currency, there is an interval of 60 to 90 days. Capital is tied up for three months, the miner objects to waiting, the smelter objects to loaning money even on so good a collateral as gold ore. The result is a compromise by which the miner pays his share—and sometimes more—of the interest on the suspense account.

Most mining districts begin to market their ores by shipment to the nearest smelters or custom-mills. They pay through the nose for treatment and transport, but they cannot escape this tax on their production until the reserves of ore warrant the erection of local mills. Moreover, in the early days of development it is not certain what is to be the average character of the ore and it is not possible therefore to ascertain the most suitable method of reduction. Usually a 5-stamp mill is the pioneer metallurgical unit. At Goldfield, the owners of the Combination mine were the leaders in local metallurgical research. From December 1903 to May 1905 the ore was shipped to the smelters; first it was hauled in wagons to Candelaria, a distance of 65 miles; later, on the completion of the railroad to Tonopah, it was carried thither, a distance of 30 miles. The distance was halved and time was saved, but the cost of transport remained much the same. It was decided to erect a mill at the mine. Tests were made in San Francisco and at the mine by F. L. Bosqui. It was found that crushing dry, followed by cyanidation, left some coarse gold undissolved in the tailing. Amalgamation was needed to supplement cyanidation. A small portion of the oxidized ore carried an excessive amount of acid due to decomposed sulphides. As much as 50 lb. lime per ton was added to neutralize this acid. Finally, an extraction of 90% was obtained on the oxidized ore. The sulphide ore, then unimportant, was more refractory. Pan amalgamation after roasting, concentration with oil, chlorination, and leaching, were tried in turn before it was decided to concentrate the rich gold-bearing pyrite, and cyanide the tailing from the sulphide ore.[1] When these tests had been concluded, a 10-stamp mill was built and to this plant 10 more stamps were subsequently added. The treatment of the sulphide ore is shown diagrammatically in Fig. 1, which is borrowed from Mr. Bosqui's description, already mentioned.

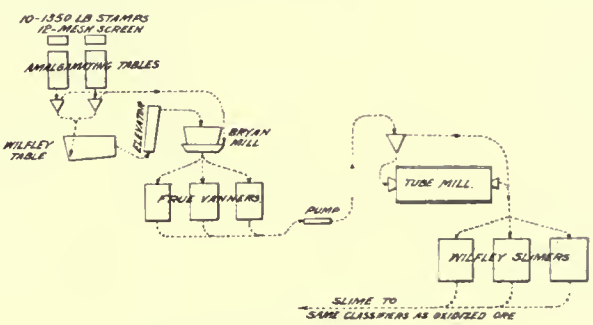

Fig. 1. Treatment of Sulphide Ore.

The Combination mill does not now impress one as a model plant, simply because it has undergone such successive additions and changes as are destructive to any unity of design, but, such as it is, this mill has solved the metallurgical problems of the district and afforded the information on which newer, larger, and prettier mills are being planned.

Before discussing the milling methods further, let us glance at the ore. It is essentially a silicified dacite enriched with gold. The altered dacite contains[2] 50% quartz, 24% kaolinite, 15% alunite, 7% pyrite, 2½% water. The alunite and kaolinite are obstacles to filtering and therefore to leaching. The alunite, being a hydrous sulphate, is destructive of cyanide and requires neutralization with lime. When the altered dacite becomes rich enough in gold to be classed as ore, it becomes more quartzose, the percentage of silica increasing from 50 to 75% or more. The ore contains pyrite (iron sulphide) in small grains, bismuthinite (bismuth sulphide) in needle-shaped steel-gray crystals, and a reddish-gray mineral resembling tetrahedrite (the gray copper of the miner).[3] The gold accompanies the gray

[1] 'Ore Treatment at the Combination Mine,' by Francis L. Bosqui. MINING AND SCIENTIFIC PRESS, October 6, 1906.
[2] 'Association of Alunite with Gold.' F. L. Ransome. *Economic Geology.* Vol. II, p. 678.

copper and the bismuthinite, the sulphides being often arranged concentrically around fragments of brecciated dacite. The native gold is rarely coarse. It occurs usually in particles so minute and so closely packed as to resemble a streak of old-gold paint. The proportion of silver to gold is as 65 to 1, so that there is a marked difference compared to Tonopah, where the silver is predominant. The Goldfield ore also contains tellurides, not in important proportion from the mineral-collector's standpoint, but enough to interest the metallurgist. Ransome mentions the occurrence of undetermined tellurides in ore from the Jumbo Extension. Lochiel M. King states[4] that, by actual analysis, he has detected calaverite, the telluride of gold, in Mohawk ore, and that he believes the greater part of the gold in the low-grade sulphide ore to be present as a telluride. The last statement is disputed by Edgar A. Collins, the former manager of the Combination mine. However, there is no doubt that tellurides exist in the ore, whether in large or small proportion remains to be proved. They constitute part of the metallurgical problem. Neither zinc nor lead minerals are noted. A little chalcopyrite has been seen in the Florence and Sandstorm mines.

The quartz, which is the predominant accessory mineral, is usually flinty in texture. Crystalline cavities are absent, but pockets of alunite are frequent. These explain the difficulty in filtering the pulp after the ore has been crushed, and the necessity for special devices in the mill. The coarseness of some of the gold aggregates explains why amalgamation is needed to supplement cyanidation. The matrix of flinty quartz encasing the finer particles of gold necessitates fine-grinding. The fineness of much of the gold justifies the use of a solvent, such as cyanide, after amalgamation. Whether roasting and dry-crushing are better than milling raw ore is a disputed question, with the preponderance of opinion in favor of the latter practice.

The Combination mill has been described in this journal by Mr. Bosqui, so it is not necessary to repeat. The same description appears in the volume entitled 'Recent Cyanide Practice.' When I went through the mill, on April 10, I noticed a broad streak of fine gold, like a band of paint, at the head of the Deister concentrating table, which receives the re-ground product from the tube-mill. This testifies to the advisability of using amalgamation. At the time of my visit the amalgamating plates in front of the stamp-batteries were blinded or covered with old vanner belts. (This was being done experimentally. In the new mill there will be thorough amalgamation before and after tube-milling.) From the battery the ore went to classifiers, the coarse passing to the tube-mill, while the fine was washed over supplementary amalgamating plates; both products went to the concentrators, one Deister and six vanners. The Deister table received the classified product, all finer than 200-mesh, from the cone-classifiers. From the vanners the pulp went to the cyanide annex. That band of gold on the concentrating table spoke eloquently for the usefulness of amalgamation. If you can save the gold at the very start, within or just outside the stamp-battery, why not do so? The metallurgist who pins his faith wholly on his cyanide annex is like the sportsman who does not mind missing with his right barrel, expecting to hit his bird with the left barrel, which is choke-bore and reaches farther. He wastes ammunition and is apt to miss his bird after all, for the farther it flies from him the more difficult it is to hit.

After the Combination mill came that of the Nevada Gold Reduction Co. This plant includes a sampler, with a capacity of 450 tons per diem, and a cyanide mill, treating 100 tons per diem. The surplus ore is sold to the smelting companies. The equipment of the mill includes 20 stamps, of 1250 lb. each, by which the ore is crushed to 12 mesh in a 0.50 to 1.25 lb. KCy solution. The pulp on issuing from the mortar goes over amalgamating plates and then to 8 Wilfley concentrators, classifying into three products, namely, concentrate, sand, and slime. The concentrate assays from $200 to $1000 per ton and is shipped to the smelters; the sand goes first to an Allis-Chalmers tube-mill, 5 by 22 ft., reducing it to a screen-size of less than 100 apertures per linear inch; from the tube the re-ground product passes over supplementary amalgamating plates and then to classifiers, the oversize from which is re-ground after going over a Wilfley. The leaching plant, which receives the pulp after the free gold and rich sulphides have been partly extracted by concentrators, includes eight vats of 22 by 5 ft. and three agitator-vats of 24 by 16 ft. Three vacuum-filters of the Butters type strain the gold-bearing solution, which is further clarified by passage through a 5-ton American filter-press, remodeled by E. S. Leaver, the superintendent of the mill.

Next in point of time, and a neighbor of the Nevada Gold Reduction Co.'s mill, is the Goldfield Cl Mill Co. This company has adopted the symbol of the chemical element chlorine as part of its corporate name. The plant is not yet in regular operation, although a trial run has been made. It is a most interesting departure and is due to the initiative of John E. Greenawalt, well known in Colorado as a chlorination expert.

The roasting furnace is a rabble roaster of the muffle type; it has a porous hearth and is heated with producer-gas manufactured from coal (coming from Helper, in Utah) enriched with crude oil (from Bakersfield, California). From this furnace the roasted ore goes to a cooling-cylinder, at the end of which it is moistened before delivery into a bin. From the bin it is transferred to large vats by means of a grab-bucket of 60 cu. ft. (nearly 3 tons) capacity, operated by a traveling electric crane. The chlorination vats are of wood, sealed by a wooden cover dipping into a launder filled with water. When silver ore is being treated 2% salt is added, before crushing, so as to get a good mixture. The leaching in the vats is done by a strong solution of chlorine

[3] I am informed later by Mr. C. D. Wilkinson that the above description is true of the Florence and Combination ores. In the Mohawk and Red Top the needle-shaped crystals do not appear and neither does the tetrahedrite. The occurrence of calaverite is still a question, as Mr. King made his determination by the ratio of gold and tellurium only; the higher-grade ore contains free gold, which will destroy this ratio.

[4] 'Cyanidation in Nevada.' Lochiel M. King. MINING AND SCIENTIFIC PRESS, January 25, 1908.

in water—7 to 8 lb. free chlorine per ton of solution. Leaching requires 3 to 4 days. The seven vats are each 22 ft. diam. and 8 ft. deep. The gold solution is withdrawn by gravity and pumped into a storage-vat and thence drawn to the precipitating-boxes, resembling the zinc-box of a cyanide plant. The precipitation of the gold is effected electrolytically, the anode being graphitized carbon and the cathode lead-shaving containing 1% zinc, the presence of the zinc hastening the corrosive action. The slime of lead, gold, and silver while still moist is mixed with flux and briquetted. The briquettes are melted in a reverberatory furnace and then refined in a cupel.

The chlorine is generated electrolytically. At first salt was obtained from Hazen, in Nevada, but it was found to contain over 5% silica, from sand blown across the dry lake; the salt now used comes from Salt Lake and costs $16.25 delivered. The solution of chlorine water is made in an absorbing tower; this consists of two sheet-iron stacks lined with glazed sewer-pipe, with cement between the pipe and the outer iron. Inside is placed a filling of hollow clay balls, each of them having eight perforations. The chlorine gas is introduced at the bottom of the stacks and water is made to trickle down from the top, the large surface thus offered facilitating absorption.

The mill has a nominal capacity of 100 tons per diem. The ore is crushed to 14 mesh and the roaster is 100 ft. long. A peculiar feature of the plant is the use of piping made of hard rubber; the pumps are actually made of it and look like cast iron until one is informed of their true composition; then they look like chocolate. Of course, iron and brass would be attacked by the hydrochloric acid, hence the use of wood in the vats and rubber in the pumps and pipes. This mill was not ready to receive custom ore at the time of my visit (in April), and yet I stated, in the opening paragraph of this article, that chlorination had been applied successfully at Goldfield. A metallurgical process is applied successfully when it yields a profit to the operator. I was referring to the use of chlorination in treating 'high-grade,' that is, stolen ore. For this purpose it is convenient, and although the percentage of extraction is not anything like that to be made by Mr. Greenawalt, it is adequate for the purposes of a 'fence,' where only 50% of the value of the gold in the stolen ore is received by the thief.

Mr. Greenawalt is an enthusiastic chlorinator and deserves success. His mill should afford a market for the rich concentrate obtained as a by-product in the cyanide plants. Mr. Greenawalt keeps some gold leaf on hand and performs a simple experiment to illustrate the greater efficiency of chlorine as a solvent compared to cyanide. In one beaker he placed a 5-lb. or 0.25% cyanide solution and in the other a 7 to 8-lb. or 0.33% chlorine solution. Dropping a fragment of leaf gold into both of these solutions, it was seen that the chlorine dissolved the metal instantly, while the cyanide had not completely eaten up the gold in an hour, a few particles of gold remaining at the bottom of the beaker, where oxygen was not available. It may be proper to point out that gold leaf does not exactly simulate the condition of gold in ore; further, cyanidation may be possible without previous roasting, but chlorination is rarely successful on raw ores. In cyanidation, the rate of solution decreases rapidly as the particles of gold increase in size, and in this respect chlorine is a more energetic solvent.

On the northwestern slope of Columbia Mtn. the Goldfield Consolidated Mines Co. is building a large stamp-mill and cyanide annex, in which will be made available all the experience obtained in the Combination mill and the other plants treating ores of similar character. At the time of my visit the concrete foundations were being laid at the rate of 100 cubic yards per day, these operations being facilitated by a crushing-plant, the rock used for concrete passing first through a Gates gyratory crusher and then through a Dodge jaw-breaker; then the broken stuff was elevated to a trommel, the oversize going to bins above a concrete-mixer and the undersize to rolls, which reduced it fine enough to make sand. This sand was an angular product well suited for making concrete. The cement comes from Iola, in Kansas. Fully 5000 cu. yd. of concrete will be required. Five thousand barrels of cement have been ordered, at a cost of $4 per bbl. delivered. A barrel holds 380 lb. On my way to the mill-site I saw a clever device used in grading for a new reservoir, to be connected with the new mill. A piece of sheet iron (an old turn-sheet) ¼ in. thick, 5 ft. wide, and 12 ft. long was being used in place of a dump-cart, as shown in the photograph (Fig. 3). The broken rock was shoveled onto this piece of sheet iron, and it was easy to roll rocks upon it (avoiding any lifting) and then to drag the load to the dump, where it swung over the edge so as to discharge itself automatically. This reservoir is to be made by using the solid rock for a back wall and half of the sides, simply plastering the surface to make it water-tight. The dimensions are 65 by 150 ft., and 15 ft. high. Steel would have cost $14,000, wooden tanks $10,500, concrete construction as outlined above will cost only $8000.[5]

On arrival at the mill-site, I found a scene of great activity, for the foundations of the ore-bins were being laid, and in the temporary office I met F. L. Bosqui, metallurgical engineer, who worked out the scheme of treatment; G. B. Shipley, the representative of the Allis-Chalmers Co., which has obtained the contract to supply the machinery; and J. B. Fleming, the mechanical engineer for the Goldfield Consolidated Mines Company.

The mill is two miles north of the mines; the ore will be transported over a railroad in 25-ton hopper-bottom cars and deliver into a bin of 850 tons capacity. The mill is expected to treat 600 tons per diem. From the bins the ore passes to a Gates gyratory crusher, which delivers it by elevator to a revolving screen (4 by 14 ft.) having 1½-in. aper-

[5]In response to a later enquiry as to the progress of the work, I am informed by Mr. J. H. Mackenzie, the general manager for the Goldfield Consolidated Mines Co., that the construction of a concrete reservoir has been abandoned owing to the time required. A water-supply is needed forthwith. So eight tanks made of redwood and 30 ft. diam. with 20-ft. staves will be placed on the reservoir site and two of the same size at the mill. The total capacity will be 1,000,000 gallons.

tures. The undersize goes to a belt-conveyor; the oversize goes to two Gates crushers and then to the belt-conveyor. This is 26 in. wide; it elevates the final product from the ore-breaker up a slope of 20° and 370 ft. long, through a Blake-Denison weighing-machine, into the sampler. From the sampler the ore is distributed by a belt running over the mill-bins, which have a capacity of 4000 tons. Suspended Challenge feeders deliver the ore into 20 mortars, each containing 5 stamps. The mortars are of the narrow Homestake pattern, but with broad bases and extra heavy, set on concrete blocks. After being crushed under the 1050-lb. stamps the ore passes over amalgamating plates made of silver-plated copper, 5 ft. wide by 16 ft. long. Thence the pulp descends to 20 double-cone classifiers, of 24-in. diam. The overflow passes directly to concentrators while the underflow goes to 6 Dorr classifiers, which thicken the pulp previous to its introduction into

Fig. 2. Blasting for Mill Foundations.

tube-mills. There are six tube-mills, each 5 by 22 ft., of the Allis-Chalmers trunnion type, lined with 4-in. silex blocks. The product from the tubes is classified in four 48-in. double cones, the overflow from which passes to 14 secondary amalgamating plates, while the underflow is returned to the tube-mills.

The slimed pulp, of which 80% will pass a 200-mesh screen, joins the overflow from the secondary amalgamating plates and proceeds to the concentrators. Concentration will be done in one stage only, namely, after tube-milling. The concentrator used will be either the suspended Frue vanner or the Deister table, and 60 machines will be required. The stream from these vanners will join the overflow from the Dorr classifiers and pass to the settling department. This consists of 16 tanks of 30 ft. diam., 12 ft. deep, provided with 16 cone-bottoms. In these tanks, by means of serial decantation, the pulp will be reduced to a consistence of 50% moisture. Then it will be transferred, partly by gravity and partly with the aid of a large centrifugal pump, into steel agitator-vats operated on the air-lift principle and known as Pachuca tanks. There will be ten of them, 15 ft. diam. and 45 ft. deep. The water overflow from the settlers will be conveyed to a series of clarifying tanks and raised to the mill-reservoir, whence it will be again put into circulation through the mill.

From the Pachuca agitators, where the pulp will be circulated in a cyanide solution for 10 to 18 hours, the material will be transferred to large reservoirs, in which it will be kept in gentle motion by means of a stirring mechanism, and from these reservoirs it will be drawn by gravity as required into the boxes of the Butters filters. There will be two of these boxes, constructed of steel and with a capacity

Fig. 3. Grading for Reservoir.

of 168 filter-leaves. After the deposition of the cake on the frames the surplus pulp will be drawn off by gravity into a large vat on a lower level. Similar vats will be provided for both water and solution, that is, the Butters plant will be operated by gravity throughout.

The solutions from the Butters filters will be clarified in three Perrin filter-presses, each having 50 frames 36 in. square. From these clarifying presses the solution will be drawn to the precipitation vats, where zinc dust will be added in accordance with the Merrill method. The precipitate will be gathered in four 30-frame Merrill presses, and the product melted direct (without acid treatment) in five Faber du Faur tilting furnaces.

The experience of several years in the Combination mill, and special experiments besides, justifies Mr. Bosqui, the consulting metallurgist to the Consolidated Company, in expecting an extraction of 95% of the gold, the silver content of the ore being negligible. The total cost of milling is to be under $2.50 per ton—a low figure, having regard to the high prices of water, power, and labor in this locality.

DIFFUSION AS A FACTOR IN ORE DEPOSITION

Written for the MINING AND SCIENTIFIC PRESS
By LEWIS T. WRIGHT.

In an interesting article by F. Lynwood Garrison, on 'Metallic Sulphides in the Tuffs of Santo Domingo' published in your issue of September 7, 1907, an occurrence of mineralization is described and his description may be summarized as follows:

In a hard tuff, difficult to work and noticeable for its absense of cracks, seams, or ducts by which an aqueous medium could travel, copper minerals are found localized in spots. These mineralized spots or streaks have the appearance of veins; but are distinctly discontinuous and erratic. The ores appear to be magmatic segregations and not veins, fracture zones, nor deposits in pre-existing cavities. The possibility of these orebodies being magmatic segregations is thereupon discussed by Mr. Garrison, but this possibility is promptly dismissed by him because the fragmentary structure of the tuff had not been destroyed by fusion, and there having been no fusion, there could have been no solution and no molecular flow or diffusion in accordance with Soret's principle of a molecular concentration caused by differences of temperature.

In the sense of Mr. Garrison's article "magmatic segregation" means a solution of metallic substances in a fused magma and the segregation or concentration of these dissolved metallic substances by their molecular flow within the solvent, according to Soret's principle, during the cooling of the magma to its freezing point. Magmatic segregation in the above sense is and has been frequently discussed, and with special emphasis by Vogt, as an explanation of certain forms of ore occurrence, and should be recognized as a distinct process from the mechanical magmatic separation or differentiation of metallic bodies entrained and mixed, but not dissolved in a fused magma—a separation acting by means of gravity, and not by Soret's principle. Also the successive crystallizations which occur in order with the cooling of the magma, and may be called chemical differentiation within a magma, are not to be confounded with a concentration by Soret's principle. Let us pause and consider what could have been the effect of a molecular flow or diffusion according to Soret's principle in connection with metallic segregations, accretions, aggregations, or concentrations of orebodies occurring in or in contact with eruptives. What in fine is 'Soret's principle'? Soret by experiment with homogeneous aqueous solutions proved that the concentration of the solute was greater in a part of such solution that was maintained cold than in a part maintained at a higher temperature. The numbers he published did not suggest that there was anything more than a slight concentration, and nothing that would amount to a 'segregation'. His number and the work of others suggested that the concentration is inversely proportional to the absolute temperatures of the hotter and colder portions of the solution, that the concentration is greater in the colder part, in proportion as the absolute temperature of the hotter is to that of the colder portion. That is to say, if in a body of solvent the upper half were maintained at a temperature of 1°C. and that of the lower half at 0°C., then the concentration of the solute in the lower half of the solution would approximate that of the upper half as 274 to 273. We have in our metallurgical experiences opportunities of observing this class of concentration of a solute in a solution.

Let us take a well settled and fluid slag from a copper-smelting furnace and let it commence to cool in a slag-bowl, and when a sufficient shell of solid slag has formed pour off the molten interior. Rejecting the top crust and the bottom of the cone in which gravimetric influences of molar separation may interfere and on assaying the side portion first-solidifying and the interior portion separately, we find a concentration of copper in the first-cooled portion similar in extent to that found by Soret. For instance as an average of a number of such trials I have found such a ratio of copper in the first-cooled slag as 1.2 to 1 in that of the last-cooled. Had the freezing point of the slag been 1100°C. or 1373° absolute, this would indicate a temperature of the interior molten slag at the time of setting of 1375°C. or 1648° absolute. Let us suppose the dissolved copper in the slag had been 0.2%, then that of the small portion first cooled would be less than 0.25%. There is a concentration, but it is trifling and totally unimportant as a molecular segregation in the sense of the cases of ore-occurrence it has been used to explain. The concentration by molecular diffusion due to difference of temperature ceases as soon as the colder portion becomes solid and this sets a sharp limit to the extent of the influence of this principle.

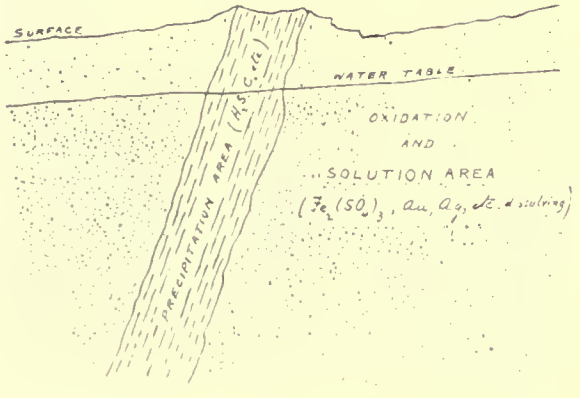
Imagine a fused rock-mass containing in solution 0.01% of a metal, say copper, at a temperature of 3000°C., and the periphery of this mass gradually cooled to its freezing point, say of 1000°C. The molecular diffusion in solution ceases so far as this periphery is concerned when it solidifies, and at that moment the pressure of the solute, in the two parts of that magma regarded as a solvent, is as 3273 to 1273, and the concentration of copper at this limiting temperature of 1273° in the periphery would be represented by about 0.026 per cent. I suggest that a consideration of the extent to which molecular diffusion by 'Soret's principle', and depending upon temperature-differences in rock magmas, can influence the formation of orebodies by concentration, shows it to be so insignificant as even to be fatal to the argument it is called upon to support.

Mr. Garrison has proposed as a basis for a theory of genesis, that would explain the one occurrence described by him in the article in question, a concentration by capillary circulation, and Courtenay De Kalb, in a more recent issue ('Diffusion as a Factor in Ore Deposition', MINING AND SCIENTIFIC PRESS, February 15, 1908), has discussed the cognate but possibly more general and frequent means of transport of minerals by means of its diffusion in aqueous solution in the following words: "Where metasomasis occurs osmotic pressure is capable without necessary movement of the solution itself, of contributing material to continue the reaction, and

that for this office saturation of the solution is not essential."

The osmotic pressure happens in solution, not only when metasomasis occurs, but always, and its effect in adjusting an equilibrium throughout the solution is brought into play whenever any change in concentration takes place in any part of the solution.

It is surprising that the transporting power of solutions at rest in which the solute will always seek to maintain the same degree of concentration or osmotic pressure throughout, has not been more discussed, in connection with ore concentrations. Van Hise in 'A Treatise on Metamorphism' discusses this transport by diffusion very clearly (pp. 82 and 637 to 639) and includes it as one of the causes of cementation. By means of diffusion or osmotic pressure solution taking place in one part of a solvent will tend to produce a uniform degree of concentration throughout the whole body of the solution, and if, at any point in the solution, there should be taking place a precipitating action, which was removing the solute from solution, the rest of the solute in



the body of the solution will tend to flow by diffusion to that point until an equilibrium of osmotic pressure is re-established, and if the precipitative action continued, the solution of the soluble substance will continue to exhaustion. Thus it is conceivable that a substance small in proportion to the containing rock may be dissolved and moreover transported to another point and there precipitated from the water which can thus act as a carrier while not moving or circulating in any manner. There is no need to conceive of any flow or stream or circulation of water as necessary for the transport of material at one time and place dissolved and at another time and place precipitated. The property of diffusion will perform this work. On the other hand, Soret's principle is a case of diffusion operating within the limits of osmotic pressure as affected by temperature-difference, and this temperature-difference is limited by the fusion point of the magma. The case suggested by Mr. De Kalb might be illustrated as in the accompanying diagram.

In a mass of rock containing iron minerals and a minute trace of gold, the water generally is taking up into solution, with the aid of dissolved oxygen, iron as ferrous and ferric sulphates, and incidentally some gold. The water filling the interstices of the rock absorbs oxygen at its upper surface, and this by diffusion penetrates more or less deeply forming iron sulphates from minerals contained in the rock. These iron sulphates tend to diffuse equally throughout the water. To the left is a sheared or fractured area or zone through which is entering hydrogen sulphide. In this area will be precipitated the iron and gold, and a fresh supply of iron and gold will continue to flow by diffusion to replace that precipitated. This action would continue until the rock in the oxidizing and solution-area was exhausted of such of its soluble content as was precipitable in the precipitating area. The precipitating area may not contain veins, fissures, cracks, seams, fracture zones, or pre-existing cavities, but nuclei or points acting as starting points of crystallization, and then, if conditions favorable to metasomasis exist, the concentration of minerals would take place.

I would offer as an extension of Mr. De Kalb's suggestion the following: Wherever from a solution, saturated or otherwise, a dissolved substance is removed by precipitation, then by the property of diffusion, without any movement of the solution itself, there will be transported fresh supplies of the substance to that part of the solution from which it is being removed by precipitation, and, if the precipitation continues, this will go on until the whole of the soluble substance has been dissolved and precipitated.

It will be appropriate while considering this matter to call attention to the well known property possessed by silica (in common with many other substances) of forming gelatinous masses or jellies while existing in what is termed the colloidal condition as distinct from crystalline forms. The jellies of colloids, even if set, allow the diffusion of dissolved salts or crystalloids to take place through their body almost as readily as this diffusion would take place through water. The colloidal jelly is a plexus of amorphous solid spread throughout water, which occupies the channels and spaces between the amorphous molecular aggregations. Free silica occurs to an enormous extent in the earth's crust, and often in the amorphous form. It should also be remembered in this connection that the amorphous forms of many substances are known to change to crystalline forms. It is conceivable therefore that much of the crystallized silica existing now as such in nature may have first been deposited or formed in the amorphous and colloidal form, and while in this colloidal form have been penetrated by other bodies in aqueous solution which bodies have crystallized or precipitated out while the silica was gelatinous, this silica afterward assuming a crystalline form. I make these observations, believing that even though flow of minerals by aqueous diffusion in rocks may not be the predominant agency by which ore deposits have been formed it nevertheless must have been frequently in operation.

Vanadium in steel increases the elastic limit, without lessening the ductility. It also enables steel to withstand more severe and continued strains. Recent tests by Richard Moldenke indicate that vanadium increases the strength of gray cast-iron 25%, while it fully doubles the strength of white-iron castings.

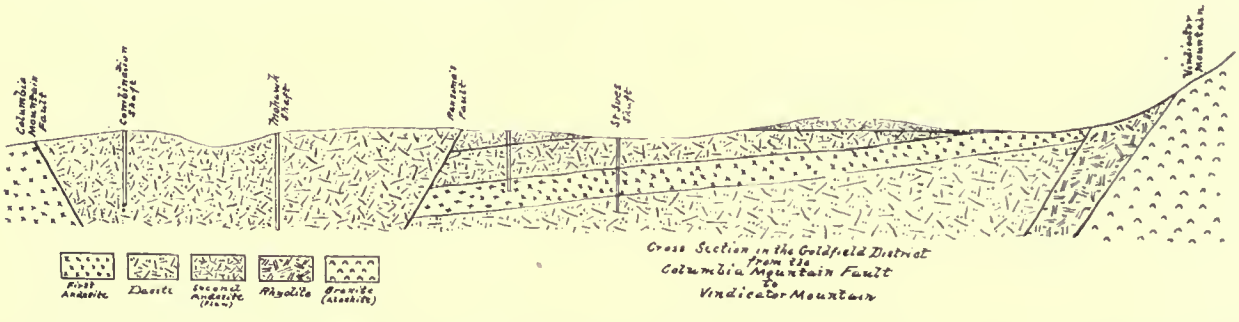
GEOLOGICAL POSSIBILITIES AT GOLDFIELD.

Written for the MINING AND SCIENTIFIC PRESS
By ARNOLD BECKER.

Any notable extension of the producing area of Goldfield (Nevada) would be welcomed, not only in the district, but throughout the country, as a matter of much commercial importance. The gold output of that small acreage covered by the Goldfield Consolidated and Florence properties has, during the past three years, been so extraordinary for a new district, that the attention of investors and operators has been very closely centred upon it, and to the neglect of a belt lying east of the Red Top, Mohawk, and Jumbo mines that seems worthy of more serious development than has yet been attempted.

The region in question differs from that of the proved belt by reason of a fault, noted by Ransome in his monograph on the geology of Goldfield; this fault strikes roughly north-south and to the west of the St. Ives and Velvet properties. West of this fault, and extending to the Columbia Mtn. fault, is an area of dacite which has not been bottomed at 600 ft., the deepest workings in the Mohawk mine and in the district. East of the fault and extending to the granite of Vindicator Mtn., is an extensive area, over part of which dacite appears at the surface. This dacite is of shallow depth—from 100 to 200 ft.—and is underlain by a sheet of the early andesite of the region. This, in turn, at depths varying, as far as I have observed, from 200 to 350 ft., is underlain by a second sheet of dacite. The importance of this fact, from a geological viewpoint, is great. The commercial possibilities can be appreciated only by those who know the relative value of dacite among the country-rocks of the Goldfield district. Of the rocks named only three need be here considered: The earlier andesite, whitish-gray, containing much hornblende and thereby readily distinguished, which is the prevailing country-rock west of the Columbia Mtn. fault, and in which no payable veins have so far been found at Goldfield, in spite of much development; the later andesite, dark gray, with phenocrysts of feldspar and with a fairly smooth cleavage; and dacite, similar chemically to the later andesite but distinguished by a rough cleavage, the presence of occasional quartz phenocrysts, and a lighter color when weathered. The first of these rocks has apparently no commercial importance whatever. The second has possibilities, as indicated in the Daisy mine at Diamondfield. The third, dacite, is the country-rock of the Mohawk, Red Top, Combination, Jumbo, and Florence mines. It is sufficiently obvious that operators at Goldfield, having before them the remarkable yield of these mines, should seek to develop veins occurring in the same country-rock and close by. That this has not been done more vigorously is doubtless due to lack of understanding of the geology of that part of the district.

In the belt with which this article particularly deals, several properties have yielded pay-ore, some of it rich, from veins that continue downward strongly as far as developed—but always, with one exception, from near the surface. Among these properties are the St. Ives, Velvet, Blue Bell, Blue Bull, North Star, and Cimmaron. Always the ore ceased, or nearly so, as the underlying andesite was approached. The exception is the St. Ives, where both the mine and lease shafts have penetrated the lower dacite, wherein, I am credibly informed, high-grade ore has again been found. This is the sole evidence, so far, that this lower dacite sheet is of the same character as that of the Mohawk-Florence belt; but it would seem sufficiently good evidence to encourage owners of neighboring claims covering strong veins to develop deeper into country that is favorable. Heretofore, operations have generally ceased as surface ore failed. In some cases, large sums have been spent in developing veins within the andesite sheet at depths of from 200 to 300 ft. with entirely negative results. A like expenditure, at a depth of 500 ft. might possibly have developed good mines.



The dacite of the Goldfield district is later than the first andesite and appears as intrusive sheets, lying rather flat and presumably following lines of weakness. Ransome notes a single such sheet, which appears at the surface, and the underlying first andesite. The lower dacite sheet does not come to the surface anywhere, but is shown in several shafts; the most westerly of these being the St. Ives and the most easterly the Old Kentuck, near Vindicator Mtn. How thick this lower sheet may be, there is as yet no evidence; but that it is of the same origin as the upper sheet, thrown off from the same more or less vertical intrusion, I can see no good reason to doubt. It follows, logically, that there may be several such sheets separated by the older country-rock. It also follows that if Ransome's north-south fault is normal, as it probably is, the first andesite of the St. Ives will be found to underlie the dacite of the Mohawk and Florence mines at a depth yet to be determined. In such event, there will be consolation in the fact that a lower sheet of dacite is known to exist and that all the evidence shows the veins to continue uninterruptedly through these variations of country-rock.

MICHIGAN COPPER MINING METHODS.

Written for the MINING AND SCIENTIFIC PRESS
By LEE FRASER.

Throughout this region different systems of mining prevail, in accordance with the dictates of necessity and circumstance. In the great majority of properties the mining companies hold the land upon which the vein outcrops, which expedites exploitation, for the lodes can be worked directly from the surface by a system of incline shafts. But, in other cases, as in that of the Tamarack and the Allouez, it was necessary to sink shafts, vertical in the case of the Tamarack, and varying only slightly from the perpendicular in the Allouez mine, until the lode is reached, when the shaft turns with the lode.

It is impossible to state the aggregate length of the workings in the copper lodes of this district. In many places cross-cuts and drifts honeycomb the vein to depths of 3000 to 5000 ft. It is almost useless to try to convey any impression of the great amount of ore that has been mined. To say that if all the ore were made into a tower 10 ft. square it would extend into the air a distance of 650 miles, and perhaps endanger the equilibrium of the earth, would leave one as much in ignorance as before. Or if it were said that the copper produced from the Lake mines would conveniently connect all the principal planets in a telephone system, with enough left over to make a girdle for the earth, we would still be unable to appreciate how much copper had been produced.

The Tamarack mine holds the distinction of being the deepest mine in the world, and is the 'deep level' of the Michigan copper country. There are five shafts on the Tamarack property, two of which are practically idle. No. 3 shaft is about 5300 ft. deep, intercepting the lode at a vertical depth of 4185 ft. No. 5 shaft is a close second at about 5250 ft., and cuts the lode at a depth of 4662 ft. No. 1 shaft, that has been idle in consequence of a fire that has been burning in the underground workings since January 1, 1906, will probably never be re-opened, since movement of the ground has so badly disturbed the shaft that it would require an immense amount of time and money to again put it into service. This shaft cuts the conglomerate at a depth of 2270 ft. and reaches downward a total distance of 3409 ft. No. 2 shaft has undergone extensive repairs during the past year and is now producing ore. It was found that the shaft had been drawn out of line by the crushing of the rock, necessitating re-timbering from top to bottom, many of the old timbers having to be replaced by new ones. The pressure of this moving ground is sufficient to break and twist huge timbers as if they were toothpicks. Even shaft-timbers of the largest dimension are broken and twisted into grotesque shapes. On the other hand, timbers have been compressed from 30 in. diam. to less than 10 in., in which condition they are as hard as flint, and defy the attacks of a saw or axe. Among mine engineering achievements the deep-level shafts of the Tamarack, and the Red Jacket shaft of the Calumet & Hecla, take a high rank. The Red Jacket shaft measures 14½ by 24½ ft. between timbers, is divided into six compartments, and extends 4900 ft. into the bowels of the earth. It is one of the largest, deepest, and most expensively equipped shafts in the world, but the shafts of the Tamarack are deeper, although not so large, No. 5 measuring 27 by 7 ft., inside timbers. Some inconvenience has been occasioned in the Calumet & Hecla by creeps and other movements of the country rock, but so far the Tamarack shafts have remained intact.

The lode in the Tamarack is reached by a system of cross-cuts driven through the country rock at intervals varying from 60 to 120 ft. down the shaft. As the work is carried deeper this necessitates much expense and labor. At present an incline shaft is being planned to be sunk parallel to the lode at a distance of 600 or 700 ft. in the foot-wall. The Osceola amygdaloid, which parallels the bed of conglomerate, can thus be worked profitably if desired. The expense of mining in the Tamarack has increased along with the opening of the deeper levels, but it is hoped that much labor and expense will be saved by abolishing the long hauls through cross-cuts. The conglomerate is usually heavy ground and requires timbering at every stage for the protection of the workmen, adding a great but unavoidable expense, for it is estimated that from 8,000,000 to 10,000,000 ft. of timber go into the mines annually.

A serious problem, which will require much consideration as the mines become deeper, is ventilation and the reduction of the temperature. In the Comstock mines the temperature often rises to 150°F., but in the Lake Superior mines the high temperatures are due entirely to depth, increasing 1°F. with every descent of 212 ft. The rock temperature now stands at about 78°F. in the lowest levels. The air is cooled by powerful fans, but these will soon prove insufficient to maintain a temperature in which the miners can work. The method of mining in the Tamarack consists generally of cross-cuts driven in from the shaft at right angles to the drift. The drift is being pushed forward on each side of the cross-cut while the ground is opened up by the 'back stoping' method, characteristic of this region. The raises are usually carried to the levels above when the work is begun on either lower corner of the block of ground which is left standing. Midway between the longer levels sub-levels or intermediate levels are driven, which present more working surface and open up more ground. The upper block of rock is taken down first, while the stope is filled with loose rock, which forms the most stable support for the hanging wall. The rock is then trammed out to the end of the level and dumped into chutes, from which it is carried to the shaft and thence to the surface. Endless-rope haulages are used whenever practicable. In some of the deeper levels the ore must be taken a distance of nearly a mile and a half before it reaches the surface.

The Calumet & Hecla encounters the same difficulties in mining as are met in the Tamarack. In both mines the ground is heavy and dangerous if left unprotected for any length of time. But it is singular to note that in both mines the death rate from accident to miners is comparatively small, and its

insignificance is marked by comparison with the deaths in coal mines due to loose unprotected ground.

One system, fast being supplanted by a newer and less expensive method, similar to that used at the Tamarack, is the square-set system. The sets are put up directly the ground is opened, but because of the enormous pressures exerted upon them are soon crushed, but not before the ore has been removed. A great amount of timber is used annually in this manner, but as in the Tamarack, the use of heavy supports are unavoidable, 20,000,000 to 30,000,000 ft. of timber are consumed every year in the underground workings. The square-set system is being

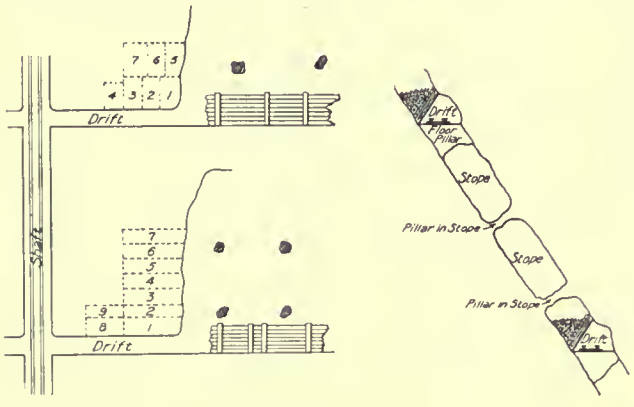


Fig. 1.

abandoned in favor of hardwood stulls, which are placed beneath the weak sections of the hanging wall.

The underground workings of the Calumet & Hecla are perhaps the most extensive of any mine in the world. The entire mine has twenty-one shafts, two of which are out of commission and four permanently abandoned. The strike of the lode averages N.39°E., while the dip is approximately 37° 30′. The conglomerate for two miles along the outcrop

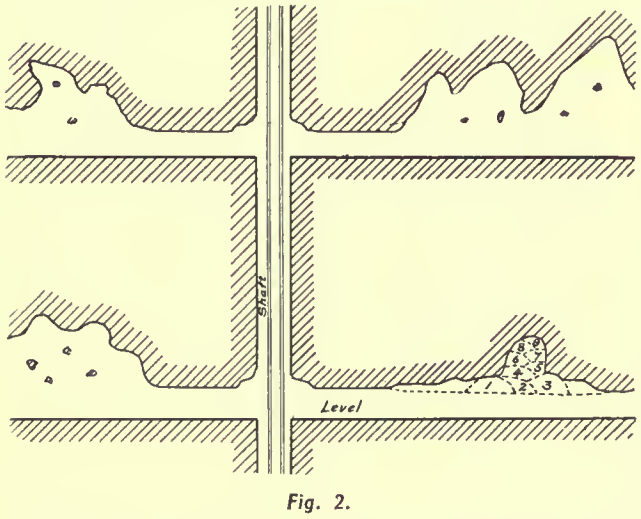

Fig. 2.

is opened by eleven inclined shafts and the six-compartment Red Jacket or Whiting shaft, while 730 ft. to the east of the conglomerate five shafts are sunk on the Osceola amygdaloid, and still farther east three more upon the Kearsarge lode. The workings of the conglomerate lode are the oldest, comprising more than 200 miles of shafts, drifts, winzes, and gang-ways. The mine is opened ahead for eight years' work. The shafts running parallel to the lode and dipping 37° 30′ are sunk to great depths. No. 4, Calumet, a single-compartment shaft, is sunk parallel to the lode a distance of 8100 ft., while a winze 190 ft. long at the bottom prolongs the depth to 8290 ft. No. 7 and 8, Hecla, both one-compartment shafts, are at present about 6300 ft. deep, and can be sunk 2700 ft. before reaching the Tamarack boundary. The mine has suffered severely in the past from underground fires, caused by the ignition of the old rotting timbers in the abandoned workings. Every possible precaution is now being taken to prevent similar occurrences in the future, by the maintenance of a fire-signal system, shaft sprinkling, fireproofing the timber, and the establishing of fire stations, equipped with chemical fire-extinguishing apparatus, while water pipes and hydrants are scattered throughout the workings. The mines are connected throughout with a telephone system, so complete that communication may be had, if required, with Chicago or New York from the bottom levels, five thousand feet underground.

The practice of mining the amygdaloid lodes does

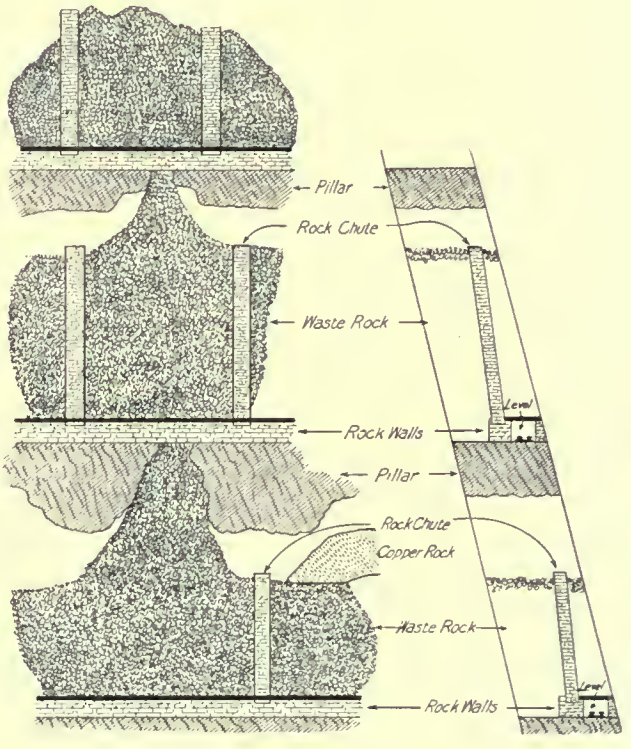

Fig. 3.

not involve the expense and dangers attendant upon mining the conglomerate, for in the Quincy, which, next to the Calumet & Hecla and Tamarack mines, is the deepest in the district, ground may be left unprotected with impunity. The practice throughout the Mohawk, Ahmeek, Allouez, Kearsarge, Wolverine, South Kearsarge, Centennial, Osceola, Franklin, Isle Royale, and Atlantic, all of which are opened upon some one of the amygdaloid veins, is identical with but few exceptions, the main differences being in the protection of the hanging above the drifts. Pillars are left in every case, the lean ore forming the pillars. The ground is brought down in successive cuts, as shown in Fig. 1 and 2. Compressed air is used throughout as the power underground for running drills, for rope haulage engines, and other purposes.

Among the mines on the amygdaloid one of the most noteworthy is the Quincy, originally opened

upon the Quincy, but now working the rich Pewabic lode. The workings extend from north to south 8000 ft., and several hundred feet upon each side, but there still remains untouched a tract of land extending about 5000 ft. north from the present workings. The continuity of the workings is broken by the Franklin mine and the Franklin Junior, lying between the two most northerly shafts of the Quincy and surrounded upon three sides by the lands of that company. The old Franklin mine seems to have approached a condition of exhaustion, but it possesses a remarkable vitality. Three hundred tons of ore are hoisted daily from the old workings. The Junior mine, working the Allouez conglomerate, maintains a production of about 1200 tons per diem. The grade of the ore is so poor that the only possibility of success is in the maintenance of a large output. Other lodes are included in the property. The management is now striving to find the Kearsarge amygdaloid, the discovery of which will greatly enhance the value of the mine, provided, of course, the copper content be sufficient to warrant opening the vein. The workings of the Quincy extend to a depth of 3000 ft. below the mean water-level of Portage lake. No. 2 shaft extends 5289 ft. from surface to the 61st level, this being next in depth to the Tamarack and the Calumet & Hecla. No. 7, the southernmost shaft, is remarkable for the rapidity with which it was sunk through hard refractory rock, the total time of sinking 4000 ft. being only 18 months. Five working-faces were constantly maintained, sinking and raising being carried on simultaneously, the shaft being sunk in close proximity to the old workings so that easy access could be obtained. The line of the shaft is a catenary curve, between 53 and 37½°, a depth of 5162 ft., nearly a mile. The Quincy mine is one of the best equipped of any operating on the Lake at the present time. The facilities for handling ore are so excellent that the managers of other companies are adopting Quincy methods with alterations and minor improvements. The principal item of expense to be considered in all the mines is the handling of a great quantity of rock at low cost. The mine has been provided with electric power and motors haul the three-ton cars to the shafts where the ore is dumped into 400-ton bins, so situated in the hanging wall as to dump directly into the waiting skips, thus avoiding delay and increasing the hoisting efficiency as much as 25 to 30%. Every effort is being made to place the mine in a healthy condition. The Quincy is troubled by air-blasts caused by the falling and settling of rock in the many miles of old abandoned workings. The falling rock causes compression of the air in other parts of the mine, and sometimes the shock of the fall and the compression is sufficient to cause a miniature earthquake that may be felt for several miles around. The disturbance comes without warning, at times killing or injuring the workmen.

Rock-Walled Gangway, Baltic Mine.

In the case of the Tamarack a perpendicular shaft intercepts the lode, but on the other hand the Allouez company sunk a shaft in the southeast corner of its property, which starts from the surface with an angle of 75° from the horizontal, but soon changes to 80° until it reaches a depth of 1435 ft. It then curves to an angle of 60°, cutting the lode at 1480 ft., and finally flattens to 38½° at the third level, thence running in the foot-wall, parallel with the lode at a short distance from it. This is a great improvement over the method adopted at the Tamarack, as the cutting of expensive cross-cuts is obviated. But it must be remembered that the Tamarack is the pioneer in deep-level mining of this nature, and the difficulties overcome were enormous. It is doubtful too whether a shaft resembling that of the Allouez would have been feasible with such a

deep property as the Tamarack. By sinking a shaft parallel and at a short distance from the lode, as proposed, the Tamarack will follow the Allouez practice to a great extent.

The methods of mining pursued in the mines of the Copper Range Consolidated differ radically from those found elsewhere in the district, and are patterned to some extent after the practice in the nearby iron mines of the upper peninsula. In the Champion, Trimountain, and Baltic mines, which are held by the Consolidated company, a system known as the 'dry wall,' or 'rock wall' (Fig. 3), has been found to give satisfactory results. The amygdaloid in these mines is not uniformly wide, the maximum being 60 ft., while oftentimes the foot and hanging walls are taken down for their copper content. The lode dips at an angle of 70°, much steeper than the others mines in the district. It flattens out toward the north, being at the Keweenaw mine only 26°. The steepness of the lode has made possible the adoption and successful operation of the rock-wall system. The rock is sorted underground, the poor rock being rejected and stowed behind. As the stopes advance upward circular rock-chutes are built up with the upper rock, down which the copper ore is thrown. Each ore-mill terminates on a level through which ore is trammed to the shaft. The method, like all innovations, was first ridiculed, but is now being adopted wherever practicable. These three mines are now in their infancy, the deepest shaft being less than 1500 ft., and as yet they have not reached their maximum production. From present indications it is safe to suppose that the members of this copper-range triumvirate will in time become the best amygdaloid mines in the district.

Tellurium in cupellation of the lead buttons containing that metal, according to Sydney W. Smith, in a contribution to the Institution of Mining & Metallurgy, results in a weakening of the surface tension of the molten metal. Cupel absorption is due to this effect of tellurium in assisting the general tendency of the film of litharge in the same direction, the result being that the molten metal tends to 'wet' the sides of the cupel. If the amount of lead is insufficient, small portions of metal become detached and either pass into the cupel or leave minute beads. If tellurium, being less easily oxidizable than lead, especially at high temperatures, remains in sufficient amount toward the end of cupellation, complete absorption may occur. Complete absorption and sub-division are entirely the result of insufficient lead. Bone-ash cupels show a greater tendency to become 'wetted,' giving rise to subdivision, than patent cupels. Silver protects gold by acting as a diluent during the cupellation of buttons containing tellurium. Absorption-loss, due to the presence of tellurium, is a function of the temperature of cupellation. During cupellation tellurium is oxidized to the dioxide TeO_2.

Coal production in France is shown by recent statistics to be only one-fifth that of Germany, one-seventh of that of Great Britain, and less than one-tenth of the production of the United States.

A NOVEL BUCKET ELEVATOR.

Written for the MINING AND SCIENTIFIC PRESS
By P. R. WHITMAN.

Two bucket elevators recently installed in the mill at Concheño, Chihuahua, while not being original, possess uncommon features. The two elevators are placed side by side, have 12-in. 8-ply belts, 7 by 12-in. buckets spaced 26 in.; head and boot pulleys 24 in. diam. The two head-shafts meet in a male and female connection, inside a loose pulley, on either side of which is a tight pulley. Thus the belt can be shifted from the loose pulley to either tight pulley, to drive one or the other elevator as desired. This arrangement has given no trouble whatever, and the feed can be shifted from one to the other without stopping the mill. The mill-flow is from 60 stamps. The belt travel is 380 ft. per minute, which gives a clean discharge. The feature which has given the greatest satisfaction is the moveable boot, hinged at the back end, entirely independent of the housing, and serving as a tightener. This entirely obviates trouble with loose and slipping belts, the attendant annoyance of hanging up the elevator, and the difficulty of having the bucket-lips catch on the bottom of the boot. By the use of slotted bolt-holes in the hinges, the axis of the boot-pulley can be shifted in two planes, thus permitting an adjustment that will cause the belt to run true, both at the top and the bottom. The feed is at the back, doing away with splash, as the buckets and pulp are moving in the same direction and with about equal velocity. The elevators lean 3 in. per vertical foot, and lift 30 ft. This was simply a detail of convenience in construction. If set perpendicularly there would be less wear on the housing from dripping, and the discharge would be equally good at the same speed of belt. The moveable boot is a great advantage, the merit of which will appeal to mill-men.

Metamorphism from combustion of oils in the bituminous rocks of California is a common phenomenon. The high temperature thus produced has converted many shales into red or rose-colored porcelain-like strata, and at times has rendered them scoriaceous like vesicular lava, or clinker. The *Journal of Geology* says that the resemblance of the products to those of volcanoes and the existence of centres like solfataras where the process of burning has been going on during the last half-century, has given rise to the statement that there were living volcanic vents in Santa Barbara county. These burned shales have been encountered down to depths of 1040 ft. in oil-well drilling. At one place fragments of such material in bedded deposits of Pleistocene age show that metamorphism of this type has been going on in remote times.

Filling of mine workings by waste flushed into the open chambers is practised at the Saarbrueken collieries, which are operated by the Prussian Government. The material used for filling consists of waste from the washeries, ashes from the boiler-plant, and other refuse. The method has given great satisfaction, but the long-wall method of mining is being substituted for other economic reasons.

BURNING LIQUID FUEL WITHOUT STEAM OR COMPRESSED AIR.

Written for the MINING AND SCIENTIFIC PRESS
By ROBERT SCHORR.

In view of the great economic results that are being obtained in European countries by the burning of oil and oil-residues under boilers and in metallurgical furnaces without employing steam or compressed air as an atomizing agent, it is surprising that the most eminent producer of liquid fuel, the United States, should have given this subject but little attention. About ten years ago the first large installations of this character were made by Koerting Bros. of Germany, on a number of warships attached to the Russian Black Sea fleet. The extremely successful performances recorded there, both from a commercial and engineering point of view, attracted widespread attention, and they led to the rapid introduction of this apparatus into almost all European navies, and also into many industrial plants where liquid fuel is being used. Among the vessels sailing from San Francisco, the Toyo Kisen Kaisha's *Sapo Maru* employs the Koerting system, using a California asphaltic oil of 16 to 17° B. gravity. This is probably the first attempt in that direction with our oils, and for that reason is of peculiar interest.

Those familiar with the burning of crude oil know that from 3 to 16% of the boiler-efficiency is consumed in the atomizing of the oil with steam or compressed air. This is equal to from 0.5 to 2 lb. steam for every pound of oil burned. Under forced conditions, as frequently met in locomotive and marine practice, somewhat better results are possible. During the Hohenstein boiler-test made by the Bureau of Engineering of the U. S. Navy, 4.2% was used on an average. Carefully adjusted burners in stationary plants will require about 5%, but ordinarily it will not be safe to figure as low as this. An additional waste of energy results in the furnace itself as the injected steam is leaving with a temperature equal to the temperature of the flue-gases. This loss will vary considerably, being governed by the original temperature of the steam in the burner, and by the temperature of the flue-gases. As the specific heat of steam is approximately 0.5, every 100° of difference between the temperatures of the steam and the waste-gases requires an expenditure of 50 B.T.U. per pound. Saturated steam at 90 lb. pressure has a temperature of 320° F., and it contains 1178 B.T.U. The 50 B.T.U. are equal to over 4% of this. Taking the flue-gases to be at 620° F., there will be 150 B.T.U. used for superheating, or about 13% of all the heat carried in the amount of steam used for atomizing. If the burner requires, for instance, 8% of the total steam raised, an additional $10.08 \times 0.13 = 1.04\%$ are accounted for in the steam escaping with the furnace gases.

The use of compressed air in place of steam frequently assures a saving, if the exhaust-steam from the compressor-engine be condensed or utilized otherwise, and if the air be thoroughly pre-heated at the burner. It gives a steady and reliable flame, while wet steam is apt to cause occasional troubles. A drawback, however, is the increased first cost, and also the danger of breakdowns. The air-compressor installation permits of a close check upon the actual work expended, but the great variance of opinion in regard to the amount of pressure best suited to the purpose, shows its bearing upon the data obtained in practice. Although air-compressors are being used extensively in connection with oil-burners on vessels sailing from San Francisco, but little definite information has been available as to the relative economies. The pressure employed ranges mostly from 20 to 30 lb., and the size of the compressor is generally based upon data obtained by experiments made with various types of burners at the Western Sugar Refinery in San Francisco. These showed that about one cubic foot of free air is required for every pound of water evaporated from and at 212°F. To compress one cubic foot of free air per minute adiabatically up to 20 lb. requires 0.0628 theoretical horse-power. To economize in first cost and in floor-space, as a rule, a direct steam-driven (straight-line) air-compressor is preferred. Assuming the efficiency of its steam end to be 90%, and of the compressor with the pipe-system to be 80%, we have a combined mechanical efficiency of 72%. Every cubic foot of free air will require then, $0.0628 \div 0.72 = 0.087$ actual cylinder horse-power. This figure clearly illustrates the importance of utilizing the engine-exhaust. The thermal efficiency of the steam-engine driving a medium sized air-compressor requiring, say, from 80 to 150 hp. will rarely exceed 9%, corresponding with a supply of 28,300 B.T.U. per hp.-hr. Adding to this approximately 7% for the condenser work, we get 30,300 B.T.U. Now, $30,300 \times 0.087 = 2636$ B.T.U. have to be expanded for 60 cu. ft. free air, furnished in the hour at a pressure of 20 lb. to correspond with the evaporation of 60 lb. water from and at 212°F. The heat equivalent of the same is 965.7 B.T.U. $\times 60 = 57,942$ B.T.U., and the 2636 B.T.U. form about 4½% of this amount. Consequently, 4½% of all steam raised is required to furnish compressed air for oil-atomizing. If we assume an evaporation of 13.6 lb. water, from and at 212° F., per one pound of California crude oil (a boiler efficiency of about 70%) 13.6 cu. ft. free air is required for one pound of oil, or less than 0.25 cu. ft. free air per minute for every pound of oil burned in the hour.

The data published in the report on the tests made with the oil system of the *Mariposa* in 1902 are not correct, and they do not agree with the tabulated items. An average of 3.9 cu. ft. free air per pound of water evaporated from and at 212° F. is given. As one pound of oil evaporated 13.53 lb. water from and at 212° F., about 0.86 cu. ft. free air per minute would have been used for every pound of oil burned in the hour, or almost four times as much as in our investigation. The tables, however, indicate that on an average 3719 lb. oil were burned in the hour. The 22¼ by 18 in. air-compressor was running at 60 r.p.m. Its figured capacity at this speed is about 1000 cu. ft. free air, and based on a volumetric efficiency of 90%, its actual output amounted to 900 cu. ft. The resulting requirement was then 900 divided by 3719, or about a quarter of a cubic foot of

free air per minute for each pound of oil burned in the hour, or the same as at the Western Sugar Refinery.

Granting that better results are possible, it is quite probable that most of our oil-burning furnaces are considerably more wasteful. In all arrangements, whether steam or compressed air be used or not, the amount of energy necessary to operate the oil-pumps and to heat the oil remains about the same. From 40 to 60 B.T.U. are required for this duty, with oil heated to about 130°F. Under given conditions, the exact pump-work can be readily ascertained, and also the amount of heat supplied to the oil. Its specific heat varies from 0.41 to 0.48. In the Koerting system no steam or compressed air is used to break up the oil into minute particles. An interesting phenomenon is utilized, which will be fully understood by studying Franz E. Junge's valuable contributions, 'Technical Aspects of Oil-fuel,' in the October, November, and December issues of the journal *Power*, 1907.

At high pressures the boiling-temperatures of all hydro-carbons and their mixtures are shifted higher up. In other words, "with rising temperature of the oils the pressure has to be increased to prevent boiling or self-ignition." The rate of evaporation at various temperatures is also clearly pictured in Mr. Junge's article for all classes of commercial liquid fuels, and the diagrams show, for instance, that American petroleum is completely gasified at 400°C. (752°F.).

In the Koerting system no effort is being made to obtain a straight gas, but the oil, after leaving the pumps, is superheated to 240 to 300°F., and kept under the corresponding pressure. A portion of the oil is gasified; the percentage of evaporation at the same temperature, however, will vary immensely with the class of oil. The superheated oil is delivered to the burners under a pressure of from 35 to 75 lb. The burners are either one or more of the Koerting's well known centrifugal spray-nozzles housed in a cast-iron chamber, which is provided with air-intake regulators. The requirement of energy for every pound of oil burned varies from 0.7 to 1⅛% of all useful work performed. The oil-pumps and the preliminary heaters require, as stated before, 40 to 60 B.T.U. The further superheating by 100 to 170°F., and a little more pump work, require additional 50 to 90 B.T.U. The limits range, consequently, between a grand total of 90 B.T.U. and 150 B.T.U. In view of the complex character and unequal behavior of various oils, and also in view of the multitude of boiler and furnace designs, it is impossible to lay down definite data.

Dynamite has been substituted for black-powder by the Pittsburg Coal Co. in its 54 mines. The initial temperature of the gases resulting from the detonation of dynamite is much higher than that of the gases produced in exploding black-powder, but the greater suddenness of the reaction and the enormous expansive effect, results in displacing the surrounding atmosphere without mixing with it until the temperature has become reduced through expansion to limits relatively safer for use in coal mines where fire-damp may be present.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

LOCATION OF MINE—'VEIN' OR 'LODE.'

The United States Statutes provide that mining claims or 'veins' or 'lodes' of quartz or other rock in place bearing gold or silver, previously located, shall be governed as to length along such vein or lode by the customs, regulations, and laws in force at the date of such location. The statutes further provide that where any person, in possession of a placer claim which includes a vein or lode known to exist within its boundaries, applies for a patent for the placer claim, but not including such vein or lode in his application, then the application shall be construed as a conclusive declaration that such placer claimant has no right of possession of the vein or lode; but when the existence of the vein or lode is not known, then a patent to the placer claim shall include and convey all valuable mineral or other deposit within its boundaries. A 'known vein or lode,' in the sense here used, is one clearly ascertained and of such extent as to render the land more valuable on that account and justify its exploitation and development. In the sense here used the term 'vein' and 'lode' are synonymous.

Noyes *v.* Clifford, (Mont.) 94 Pac. 842, March, '08.

OWNER OF SURFACE OF MINERAL LAND—RIGHT TO SUPPORT.

Where the surface soil of mineral lands is owned by one person, and the mineral underneath is owned by another, the owner of the surface has an absolute right to the necessary support for his land; and if the owner of the minerals in removing them removes the support for the surface, he is liable for all damages that result to the surface soil by reason of subsidence, regardless of how carefully or skilfully he may have conducted his mining operations.

Collins *v.* Gleason Coal Co., (Iowa) 115 Northwest. 497, March, '08.

LOCATION OF MINE—EJECTMENT.

In an action in ejectment the defendant claimed a lode-location within the boundaries of the plaintiff's placer-location; and the defendant without proof of location was held entitled to question the prima facie title of the plaintiff as shown by plaintiff's patent, by showing that the lode or vein in controversy was known to exist at the time the application for the patent was made, and that the defendant was justified in his apparent intrusion on the plaintiff's premises.

Noyes *v.* Clifford, (Mont.) 94 Pac. 842, March, '08.

MINING CORPORATION—LIABLE FOR PHYSICIAN SERVICES TO INJURED MINER.

A mining corporation was held liable to a physician for his services in treating an injured miner, where he was employed by the mine superintendent, who immediately reported the fact to the company, and its president and general manager ratified the employment and notified the physician to purchase necessary articles for the future treatment of the miner.

Cushman *v.* Cloverland Coal & Mining Co., (Ind. App.) 83 Northeast. 390, Jan., '08.

NEGLIGENCE—ASSUMPTION OF RISK.

A miner does not assume the risk of the mine-owner's negligence; and in the performance of his duties a shot-firer is not required to assume that the mine-owner has violated the statute or neglected its known obligations; and where he himself exercises the diligence required by the statute in certain work, and exercises the diligence, watchfulness, and caution which would be exercised by an ordinarily prudent man performing such dangerous service, he is not deprived of his statutory right of action for injuries, if he fails to discover the negligence of the mine-owner.

Kirby *v.* Manufacturers' Coal & Coke Co., (Mo. App.) 106 Southwest. 1069, Dec., '07.

ELECTRIC SMELTING OF IRON ORES.

An article read at the recent annual meeting of the Canadian Mining Institute, by A. Stansfield, of which the following is an abstract, presents an interesting review of the development and future possibilities of electrical power for smelting iron ores. The electric furnace has so far proved commercially successful only in the manufacture of crucible cast-steel, but recent developments indicate that it may successfully compete with the blast-furnace in the direct smelting of ore.

The most successful experiments along this line are those of Héroult and Keller in the production of pig-iron. Héroult's furnace consisted of a vertical shaft similar to a small blast-furnace, in which hung a central carbon electrode. The crucible was lined with carbon, which served as the other electrode, the current passing from the hanging electrode to the charge in the crucible of the furnace. The ore, with fluxes and sufficient carbon for its chemical requirements, was fed around the vertical electrode, the electric arc producing enough heat to set up the chemical reactions involved in reducing the ore to metal, and in fusing the resulting pig-iron and slag. The Keller furnace consisted of two vertical shafts in each of which hangs a carbon electrode, the current passing from one to the other through a connecting trough or passageway. The resulting pig-iron and slag collect in this trough. The Keller furnace has the advantage of being able to use a higher voltage than the Héroult.

Results from these small imperfect furnaces show a consumption of electrical energy of about 0.3 hp.-year and 800 to 900 lb. of coke per long ton of pig-iron. Hence, if electrical energy can be purchased at a cost per horsepower-year of less than that of two tons of coke, the electric furnace is the more economical, assuming of course, the general costs of operating the two to be the same. The electric furnace possesses other advantages, chief among which are: (1) the ability to use ore in a granular or pulverulent condition, since, in a blast-furnace, ores of this character are liable to be blown out with the furnace gases or obstruct the passage of the blast through the charge; (2) the possibility of treating titaniferous and other difficultly fusible ores, because of the higher temperature and greater consequent ease of fusing the charge; (3) the fact that in treating sulphurous ores, the higher temperature allows a larger proportion of lime to be used in the charge, permitting of larger elimination of sulphur as calcium sulphide; (4) the electric furnace does not require coke possessing the physical properties demanded in blast-furnace practice, it being used only as a chemical reagent.

Commercially, however, the electric furnace has many difficulties to overcome, one of the most important being the small scale on which, up to the present time, it has been constructed. In the Héroult furnace the height of the shaft is limited by the length of the electrode, though in an improved furnace designed by Haanel and Turnball a greater height of ore-column was obtained by a system of inclined shafts. Another weak point is the fact that no provision has been made for utilizing the heat of the waste gases, although Turnball has proposed the addition of a rotating cylinder through which the ore may be pre-heated in passing to the electric furnace.

Realizing the importance of reducing the consumption of fuel and of electric energy to the lowest possible point, Mr. Stansfield has calculated what he believes could be expected from a furnace in which the gases, arising from the reaction between charcoal and the ore, were used partly for the reduction and partly for the pre-heating of the ore. He concludes that, allowing for all losses, one quarter of a horsepower-year and 600 to 800 lb. of coke or charcoal would be required for the production of one long ton of pig-iron. No economical scheme for the direct reduction of steel from ore has ever been put in operation on a large scale. Both Stassano and Héroult have been successful in producing steel, but they abandoned the process as uneconomical. It is probable that the most satisfactory method of producing steel electrically will be to reduce the ore to pig-iron in one furnace, and convert the pig-iron into steel in another.

Electric smelting of tin ore has been experimented with by F. Matonet, and is described in a recent number of *Metallurgie*. The ore used contained 50% Sn, 7.6 Fe, 3.3 Zn, 1.9 Pb, 0.44 Cu, and 7 S. It was found necessary to roast the ore before putting it into the electric furnace. For the furnace treatment an approximately neutral or slightly basic and alkaline slag is best. A resistance furnace must be employed. The chief advantage of electric smelting is to be found in the fact that the slag will absorb much less tin as silicate and will occlude no metallic tin in the form of globules. The disadvantages of electric smelting are first the loss of tin as vapor and as dust, though this loss may perhaps be reduced when operating on a larger scale. The second disadvantage is the greater impurity of the tin produced. To remove lead from tin, a process similar to the Pattinson process may be employed. The tin product of the electric furnace contains about 2 or 3% of lead. The tin-lead alloy is heated to the melting point (about 230°C) and then slowly cooled to a temperature a few degrees above the melting point of the eutectics (180°C). This temperature is maintained for some time. The pure tin crystallizes out while the heavier eutectic mixture of 30% lead and 70% tin remains back. This may be repeated several times. By treating a 2% lead alloy in two refining processes, the lead is reduced to 0.2%. The eutectic mixture is then treated by mixing to produce an alloy containing 10% lead, which is commercially used for cooking utensils.

Marking tools with a name may be done by coating the surface with a layer of wax or hard tallow, applied when the tool is hot, cutting the desired lettering in the wax, being careful that each stroke shall penetrate to the steel, and then pouring dilute nitric acid upon the engraved wax, let it stand a short time and wash off with warm water; heat the tool until the wax melts, and wipe dry.

MINE REPORTS.

AMALGAMATED COPPER CO., NEW YORK.

The report of the Amalgamated Copper Co. is given below, without abridgment:

During the fiscal year of the Amalgamated Copper Co. which ended April 30, 1908, the fluctuation in the selling price of copper metal was greater than at any other period in the history of the copper trade. At the time of the last annual statement in May, 1907, there was an unlimited demand for the metal, the selling price at that time being in the neighborhood of 25c. per pound. This demand was afterward seriously affected by the severe financial depression throughout the country, and in the early summer of 1907 it suddenly slackened, and afterward almost altogether ceased. The price of copper meantime gradually declined; and during the last two months of the fiscal year the metal has sold at from 12 to 13c. per pound. The business paralysis in the United States, was, however, not fully reflected abroad, and most of the copper metal that was sold in the market (and this was a large quantity) was bought for European account, the purchasers taking advantage of the low price of the metal to replenish holdings, which had been allowed to become depleted during the former period of high prices. Immediately after the first falling off in the demand, there was a natural tendency on the part of the producers of copper to await better business conditions; and, during this period, as but little copper was sold, a large amount was naturally accumulated. After the price of copper had fallen considerably in the market, the officials of the various producing companies adopted the policy of curtailing the output from their respective mines at Butte. But after operating for a period of several months under curtailed conditions, during which time the producing cost was far in excess of the normal (owing to the fact that each company was producing only a small part of its normal output), it was deemed advisable to confine all operations to one unit. The mines and smelter of the Boston & Montana Co. at Great Falls were put in operation to their fullest extent, and with satisfactory results. In February, 1908, the surplus stock of copper had practically disappeared, and on March 1, 1908, the mines of the different companies and the Washoe smelter were again put into commission and are now being operated to their full capacity. The plans formulated by the engineers, mentioned in the last report, for the settlement of boundary rights and questions of apex have been in operation for over a year, and all parties having any interest in the matter have been satisfied with the results. The Tramway shaft, which has been sunk jointly by the Red Metal Mining Co. and the Butte & Boston Co., and through which it is expected that the ores from the Minnie Healey and the Snohomish and Tramway mines will be hoisted, has reached a depth of 1400 ft. below the surface, and is now being sunk to the 1500-ft. level. Cross-cuts from the lower levels of this shaft are now being driven into the contiguous territory, and the orebodies developed have been most satisfactory. The Washoe smelter, at Anaconda, has been equipped with electric power, thereby greatly lessening the cost of operation, and is able to treat 10,000 tons of ore per day without difficulty. The Boston & Montana Co. has throughout the year diligently prosecuted the improvements in its reduction works at Great Falls. All of the grading for the flues and dust-chambers has been finished, and the new stack, the top of which when completed will be 506 ft. above the foundation, has been built to a height of about 50 ft. The usual amount of development work in the different properties has been carried on throughout the year, and the results in most cases have been gratifying. The continued occurrence of high-grade ores in the lowest levels of the mines controlled by the Amalgamated Co., and in the adjacent mines of other companies, tends to confirm the confidence which the company's engineers have always had in the future of the Butte district. The saw-mills of the Big Blackfoot Milling Co. were operated to the extent required to meet the demand of the mines at Butte and the commercial trade generally. Some decrease in output was made necessary on account of the curtailment of ore-production at Butte and by reason of the fact that the demand for commercial lumber fell off materially during the financial depression. The said company has confined its operations to the timber areas adjacent to its original mill-sites. Its largest timber holdings still remain intact. The earnings for the year were quite satisfactory and the output of its mills is now normal.

The Belt mines, owned by the Anaconda Copper Mining Co., and the mines of the Diamond Coal & Coke Co. were operated with satisfactory results, notwithstanding the fact that during a portion of the year the demand for coal greatly diminished. Constant development work has been kept up throughout the year on the coal property, located at Bear Creek, Montana, and owned by the Washoe Copper Co., and the mines which have been opened have been for several months producing most satisfactorily. The quality of the coal is excellent and the field is one of great promise.

The harmonious operation of the five-year labor contract which was entered into between the employees of the different departments and the officials of the mining companies has worked satisfactorily. The companies owned wholly or in part by the Amalgamated Copper Co. produced in the calendar year 1907, from their own and custom ores, about 212,000,000 lb. refined copper, of which amount the Amalgamated Copper Co. received the benefit from about 178,000,000 pounds.

The company's balance-sheet shows net income for the year of $6,680,556, out of which dividends amounting to $6,155,516 were paid. The net income represents 4.31% upon the authorized capital of $155,000,000, nearly all of which has been issued. The investment on capital account stands on the company's books at $156,480,647, embracing all mines, plant, lands, and property of every sort, including securities.

BUTTE COALITION MINING CO., NEW YORK.

The report of the Butte Coalition Mining Co., the corporation which represents the brilliant achievement in financial diplomacy of having consolidated interests two years ago that terminated 80 pending lawsuits involving aggregate claims for damages amounting to $100,000,000, presents a report for 1907, showing an income from mine-earnings of $1,320,000 and from interest of $173,345. From the total is deducted $31,879 for salaries, office and general expenses, leaving a disposable balance of $1,461,465. The sum of $195,494 having been carried forward from the previous year, a total dividend of $1,650,000 was paid, leaving a balance $6959.

The mines worked continuously during the year up to the middle of September, when production was reduced 65%, and on December 1 production was entirely suspended. During this period of inactivity extensive development was performed in the Rarus mine, mainly on the lower levels, that is, the 15th, 16th, and 17th, the shaft having penetrated to a depth of 105 ft. below the 18th. The ore developed by this work is estimated to exceed the normal output of the mine for a year. During 1907 the stoping in the Rarus, stated in the terms adopted by the company, amounted to 2,053,055 cu. ft. of ore in place, figured from the square sets put in position, representing an advance of 9.72 miles 1 set wide and 1 set high (5 ft. by 8 ft.). Cross-cutting has shown that valuable and hitherto unknown ore-shoots exist outside of the main vein, and even in the principal veins themselves mineralization many feet beyond the walls into the enclosing granite has resulted in the formation of irregular bodies of copper-glance, many hundreds of tons of ore are being produced from such 'impregnations' alongside old abandoned stopes. One of these outlying ore-shoots has shown a volume of chalcocite which a year's stoping will not exhaust. Production in the Minnie Healey mine was interrupted in June by a fire in the old north-workings. The fire situation was taken in hand by the Boston & Montana Co., and the affected area is now well isolated. Development on the Minnie Healey has been done by cross-cuts from the Rarus, and from the Tramway shaft. The Corra main shaft was sunk to level 18, from which a

drainage cross-cut was extended through the Diamond mine to the Anaconda Copper Co.'s main pumping plant at High Ore, and arrangements have been made with the company to pump the Corra water. At the Tramway, development consists in part of sinking the 4-compartment shaft, 5 ft. by 18 ft. 10 in. in the clear, and timbered with 12 by 12 in. Oregon fir timbers. The shaft was deepened 326 ft. during the year, all compartments being sunk together. The Tramway shaft is now connected with the Rarus on levels 13 and 14, and will soon open into level 15. It also connects with the Minnie Healey orebodies on levels 10, 11, and 13, and communication will shortly be established with levels 14 and 15. This comprehensive system of development and inter-communication of workings will yield great economies in future operations, the design being that the Tramway plant shall serve the entire Rarus-Tramway-Minnie Healey group of mines. A 92-ft. steel head-frame has been erected, and elaborate equipment, including machine, boiler, and carpenter shops, tool-sharpening shop, and an elaborate change-house, with all modern sanitary arrangements, capable of accommodating 1500 miners, have been erected. The buildings are of structural iron and are entirely fire-proof.

During the period under review the mines of the company produced 377,240 tons of ore, yielding 51.47 lb. copper and 1.18 oz. silver per ton, the net yield of metals being 19,416,377 lb. fine copper, 444,809 oz. silver, and 2480 oz. gold. The report is barren of details revealing the technical and practical management of the company's operations. The cost of mining is not stated, and no data of any kind are furnished by which the capability of the management may be justified.

COMMERCIAL PARAGRAPH.

THE JEFFREY MFG. CO., Columbus, Ohio, has issued bulletin No. 24, describing their drop-rail mine-cage.

GEO. C. ROBBINS, formerly at Wallace, Idaho, has opened an assay office in the Union Trust Bdg., Los Angeles.

THE DENVER ENGINEERING WORKS announces that its Salt Lake office is now at room 316 Dooly Building.

THE H. W. JOHNS-MANVILLE CO. announce the opening of a branch office at 30 South Pennsylvania street, Indianapolis, Indiana.

THE MOORE FILTER CO., New York, has recently closed a contract with the San Rafael mine, Pachuca, Mexico, for a type A filter plant of 250 tons capacity.

WINSTON BROS., who are driving the Chicago, Milwaukee & St. Paul railroad tunnel through the Bitter Root range of the Rocky Mountains, are using twelve 3¾-in. Wood drills.

THE LANE SLOW SPEED CHILIAN MILL CO., Los Angeles, has issued the third edition of their catalogue describing the quartz-mill made by them, and include with it, a reprint of an article by C. C. Lane on 'Stamp and Chilian-Mill Experience of Forty Years.'

BOOKS RECEIVED.

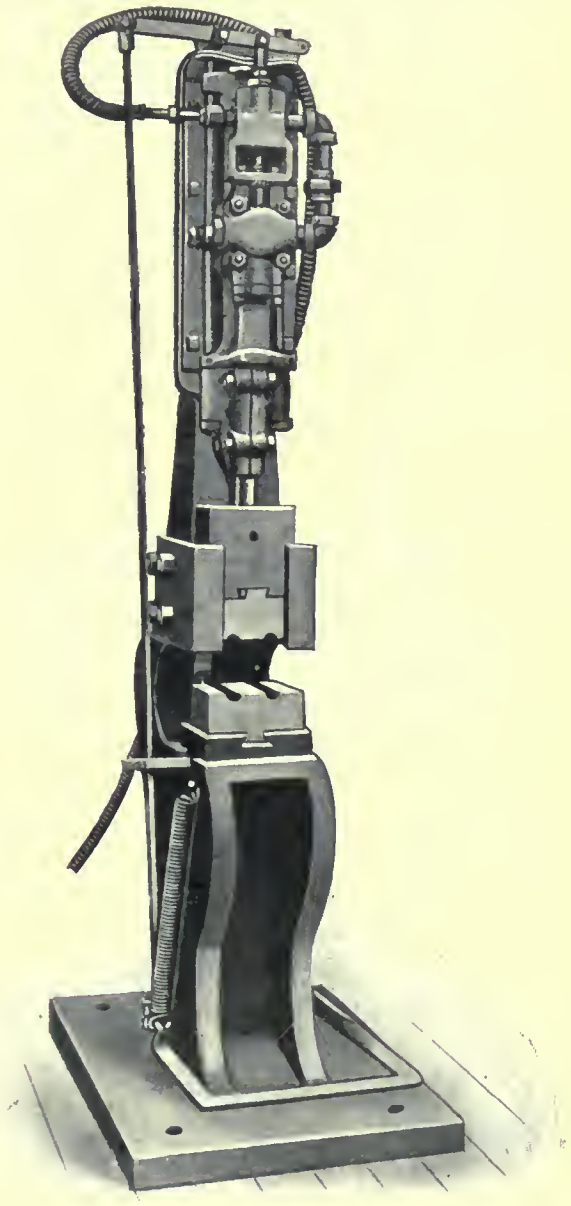
CONCRETE CONSTRUCTION. By Halbert P. Gillette and Charles S. Hill. 8vo., pp. 680. Ill. Index. Myron C. Clark Pub. Co., Chicago. 1908. Price $5. For sale by the MINING AND SCIENTIFIC PRESS.

The subject of concrete construction is presented by the author in such a way that it will appeal to contractors and, in a less degree, to designers and architects. It is one of those books which will furnish many useful hints and suggestions, but can not be considered as a complete guide. The authors give a valuable discussion of the constituent materials of concrete and the methods and cost of proportioning and mixing them. In the following pages many of the special uses and applications of concrete are described and illustrated, among them being concrete piles, bridge piers and abutments, retaining walls, pavement foundations, sidewalks, curbs and gutters, tunnel-linings, and the like. One chapter is devoted to laying concrete in freezing weather, one to reinforced concrete building construction, and another to methods of water-proofing concrete. Throughout the book much space is given to costs, and while the data are more complete than may generally be found in treatises on construction, such information must always be used with care, and is soon out of date.

CEMENT INDUSTRY IN THE UNITED STATES IN 1907. By Edwin C. Eckel. Advance chapter from the 'Mineral Resources of the United States for the year 1907.'

CONVENIENT SMALL STEAM HAMMER.

A light power-hammer is of great utility in a mine or smelter machine-shop. The accompanying illustration shows such a tool, weighing only about 2000 lb., but substantially built. It will work equally well with compressed air or steam, and consists of an adaptation of the D24 Ingersoll-Rand type of drill, with the special Ajax valve-control, giving perfect adjustment through a foot-treadle of the number and strength of the blows. The operator can control the valve from three sides of the hammer. This hammer is capable of forging material as large as 4 in. diam. It can be applied to all ordinary welding, shanking drill-steels, and even welding broken stems from stamp-mills. Yankee ingenuity has resulted in extemporized contrivances in many blacksmith shops, where old drills have been made to do such duty. But these are crude in the matter of control. It is exactly in the matter of such details that this mechanism meets the needs of the machinist. This hammer is made by T. H. Proske of Denver, Colorado.

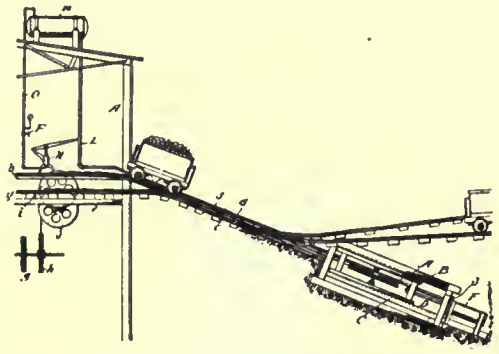


Light Power-Hammer.

MINING AND METALLURGICAL PATENTS.

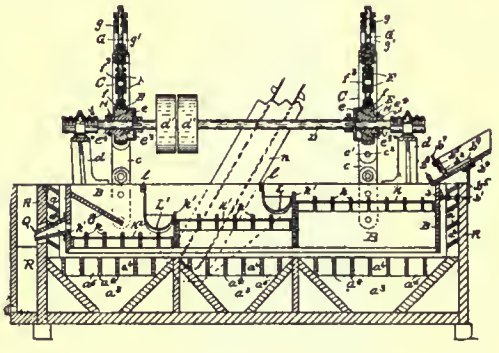
Specially Reported for the MINING AND SCIENTIFIC PRESS.

TENSION DEVICE FOR CABLE-CAR HAULS.—No. 888,439. Merrill Hibbard, Columbus, Ohio.



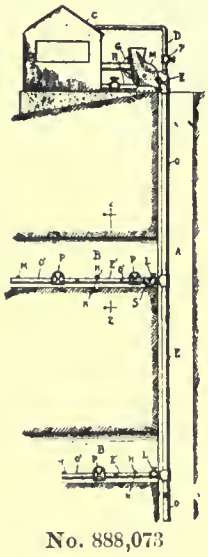
In a take-up mechanism for a cable haul, the combination with a bodily movable cable sheave or guide, and a movable holder therefor, of a cylinder, a piston therein connected with the movable holder, and means for supplying fluid pressure constantly in the cylinder against the piston, substantially as set forth.

ORE-CONCENTRATOR.—No. 887,922. George T. Cooley, Joplin, Missouri.

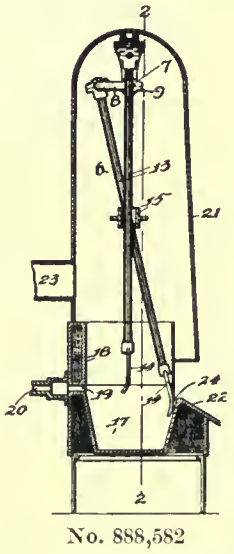


In an ore-concentrator, the combination of a tank; a frame movably mounted in the tank; a sieve in the frame; a series of partitions in the tank around the frame adapted to interfere with the movement of water in the tank; and means for imparting a combined vertical and horizontal movement to the frame, substantially as specified.

SYSTEM FOR VENTILATION OF MINES.—No. 888,073. William E. Elliott and John G. Wilson, Sharon, Pennsylvania.



No. 888,073



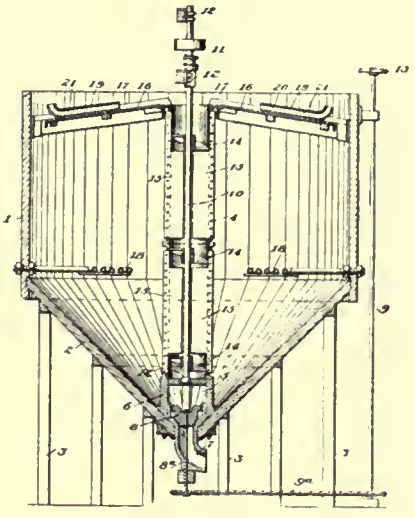
No. 888,582

In a system for the ventilation of mines, means for creating a current of air at substantially right angles to the direction of the length of a drive, said means including alternately spaced air inlets and outlets, substantially as shown and described.

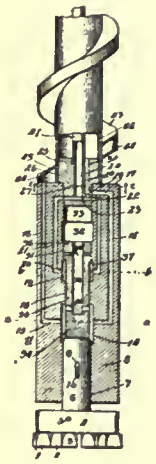
ROASTING AND SMELTING FURNACE.—No. 888,582. Josephus J. Brown, Jr., Troy, New York.

A device of the class described, comprising a plurality of agitators in combination with a roasting and smelting furnace, said agitators arranged to alternately dip into the hearth of the furnace to mix the material therein, and means for operating the agitators, substantially as specified.

APPARATUS FOR TREATING ORES.—No. 889,128. Wilbur A. Hendryx, Denver, Colorado.



No. 889,128



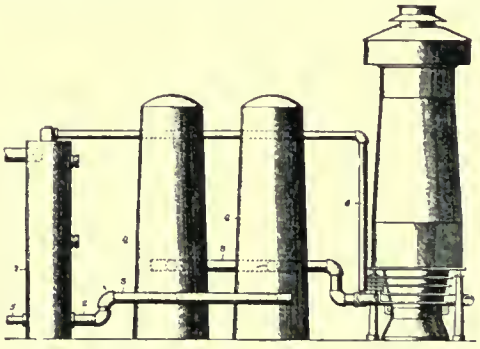
No. 888,164

Apparatus for treating ores, comprising a tank, means for continuously aerating the contents of said tank by lifting portions and moving them in a thin sheet or film in contact with the atmosphere, and electrodes disposed in the path of said lifted portions.

PNEUMATIC DRILL.—No. 888,164. Martin Hardsocg, Ottumwa, Iowa.

In a pneumatic drill, a hammer-frame consisting of a straight central barrel with oppositely running spiral flanges encircling the barrel and extending from end to end of the barrel, the barrel having a central chamber divided into sections, one section to receive a driven stem and another section to receive a driving hammer, and each spiral flange having a spiral induction passage and a spiral eduction passage, with the eduction passage of one flange terminating at the end of the flange and frame, and the eduction passage of the other spiral flange terminating in a port laterally extending inwardly, substantially as described.

ART OF SMELTING ORE.—No. 887,974. Alfred Steinbart, Pittsburg, Pennsylvania.



As an improvement in the art of smelting ore, the method herein described which consists in lessening the percentage of moisture in the air to be forced into the furnace to a point below that of saturation at atmospheric pressure and at the temperature of a natural cooling medium, maintaining the moisture at a slowly varying percentage below such point of saturation by subjecting the air to compression and to such natural cooling medium and forcing the air into the furnace.

CONGRESS appropriated $1,335,520 for the maintenance of the Geological Survey during the fiscal year 1908-09. The bill specified particular sums, as usual, which should be applied to special purposes. For geologic survey-work the amount named was $200,000, for topographic surveys $300,000, and for fuel-testing investigations $250,000. The next largest items were $100,000 each for investigations of water resources and structural materials.

THAT MOST nomadic of men, Mr. J. H. Curle, contributes an interesting account of travels in many distant corners of the world, and as usual he hits out from the shoulder in making criticisms of men and things. Outspoken comment and fearless statement of fact are a tonic without which human affairs would grow musty; the fresh air of virile criticism drives off the mildews of self-complacency and corruption. And our friend Mr. Curle is ever frank and outspoken; his analyses of mining conditions in many parts of the world, made during his career as a writer to *The Economist*, to the MINING AND SCIENTIFIC PRESS, and to other journals, have proved correct in so many cases as to vindicate the accuracy of his judgment. We hope he will avoid malarial countries and be long spared to do useful work as a journalist, skillful and fearless.

IN THE DEATH of Quincy A. Shaw, the mining fraternity has lost one who graced it with intellectual and moral character of noble type. In an epoch in which the gaining of millions has seemed but to intensify the acquisitive spirit, and to weaken regard for the rights of others, Mr. Shaw for twenty years had quietly attended to the duties of a director in the Calumet & Hecla Mining Company, without seeking to play at Napoleonic finance, despite the temptations which have never been absent from the copper market. He chose to operate the mines which he virtually controlled for the sake of the available producer's profit, with no attempt at using the great power of his position to win an unearned increment through manipulation. Mr. Shaw was noted as a practical philanthropist, and had taken an advanced position in sociological matters indicative of a sincere desire for the general uplifting of humanity. He was 83 years old at the time of his death, on June 12.

THE REFERENCE in our London letter this week to the Briseis tin mine, in Tasmania, recalls the illuminated prospectus issued as an allurement for investors in England when the company was financed, in 1899. The promises of yield per cubic yard were based upon sampling done in the crudest manner, crediting the value per foot in

depth through the narrow section of the lower enrichment to the larger area of the upper lean gravel, without corresponding reductions. Such simplicity is difficult to understand, as is also the failure of the directors to make public announcement of the fact of error when that subsequently became known.

Yukon Gold Claims.

OUR Toronto correspondent recently stated that the Canadian Minister of the Interior, Mr. Oliver, replying to an interpellation by the leader of the opposition in Parliament concerning the Government's acquiescence in the manipulations of the Yukon Gold Company, divulged the fact that the title to the claims was conditional on the performance of work to the value of $200, and the payment of a renewal fee of $15, upon each claim every year. The question put by the opposition was of a sort that arouses unnecessary antagonism, since placer mining claims in the Yukon Territory are held under licenses issued by the Gold Commissioner that must be renewed annually. It would, however, have been as well for the Yukon Gold Company to have indicated the character of its tenure in an explicit manner in its printed statement. The report declared "the company has purchased sufficient creek claims and upper level or bench deposits, to control the mining situation." The conclusion of the investor would be that the company was in possession of its ground through title, unless he happened to be informed concerning the mining regulations for the Yukon Territory. There is indeed a mention of creek 'claims,' but common usage applies that name to a patented as well as to an unpatented claim, so that no particular pains were taken to hang out the red-lantern for the unwary. Some people, perhaps many, would prefer investment in a corporation holding its ground in fee-simple. The fact that title absolute has not or cannot be obtained under Canadian laws relating to the Yukon does not justify the conclusion that the investors have been seriously or at all affected. The title of the Yukon Gold Company is good so long as the laws are complied with. Many of the heaviest mining operations in the United States are initiated upon possessory titles, which may lapse if the laws are not complied with. It would appear that the opposition assumed the position of a carping critic for no better purpose than to awaken the public to a realization of some facts of Canadian law—which may be useful. It remains to add that the tenure of mining companies in Australia, even those involving millions of dollars, and operations that have continued for a score of years, is based on leases, usually for 15 years, renewable at the expiration of the term for which they are granted, provided that the rental is paid regularly and the mining regulations duly observed by the lessee. Such tenure under an irresponsible or corrupt government would be dangerous, but so in fact might be any title under like conditions. The Yukon Gold Company's holdings are perfectly safe and if the gold is there in sufficient quantity and can be extracted at a low cost, there need be no worry as to title. That is the least of their troubles.

Reform Movement in San Francisco.

PRESIDENT ROOSEVELT never more clearly demonstrated the sincerity of his devotion to the cause of civic betterment than in his letter to Rudolph Spreckels, which we re-print in this issue. Politics are not involved in this discussion. Mr. Roosevelt can have no left-hand purposes of personal aggrandizement in view. He is uttering the deep conviction of an honest private individual in whom there is hope, as a means of inspiriting those who have to fight the battle of civic respectability against such tremendous odds of villification and indifference as to give to the struggle at times an appearance of hopelessness. So Mr. Roosevelt sounds the clear and encouraging note of undaunted confidence. Faith is one of his leading characteristics, as it must be of all men endowed with perfect health of mind and body. It is at the root of his strenuosity, which has been misinterpreted as a motive, whereas his course of action is invariably strenuous because of the vigor and faith behind it. Conscious of the evils needing correction, the reformer must still be the cheerful optimist. Complaint and lament have no creative power. The man who has force within him to move others to good and useful acts takes the lead in jovial spirit, and calls for coöperation instead of sympathy. "My thanks are due to the American people, and not theirs to me, for the opportunity I have had to serve them," said Mr. Roosevelt recently, adding, "I have had a perfectly corking time." That breathes a spirit which makes men believe in a leader, and trust his capability of making a good fight. There is breezy health in that word 'corking'. It is not in the dictionary, but there is an unmistakable snap and fizz to it that conveys an impression which all men understand, and which makes them share his moral convictions. So has his counsel to Mr. Spreckels and to Mr. Heney come in a way that will help them in good-natured determination to re-establish civic rectitude in San Francisco. It would seem that this letter had been sent at a psychological moment, when the spirit of reform was in the air and needed exactly such a stimulus to render more effective the movement which has just been set on foot by a body of San Franciscans under the name of the Citizens' League of Justice. Headed by Matt. I. Sullivan, Barclay Henley, Rev. C. N. Lathrop, Walter Macarthur, John Sweeney, George H. Boke, and W. H. Payson, this association proposes to give determined support to the courts and officers of the law now engaged in the trial of persons accused of corrupting the public honor and violating the law of this State. It will continue its existence as a guardian of the honest administration of the city in the future, becoming a centre around which the stalwart moral forces of the community may gather, and find means to do effective service through competent organization. Unlike the determined Vigilantes who in times past applied heroic remedies to restore law and order, the League expresses faith in the efficiency of the constituted authorities to mete out justice, if sustained by the properly directed sentiment of the community.

BY THE WAY.

The White House, Washington, June 8, 1908.

My dear Mr. Spreckels:

Now and then you and Mr. Heney and the others who are associated with you must feel down-hearted when you see men guilty of atrocious crimes who for some cause or other suceeed in escaping punishment, and especially when you see men of wealth, of high business, and, in a sense, of high social standing, banded together against you.

My dear sir, I want you to feel that your experience is simply the experience of all of us who are engaged in this fight. There is no form of slander and wicked falsehood which will not as a matter of course be employed against all men engaged in such a struggle, and this not only on the part of men and papers representing the lowest type of demagogy, but, I am sorry to say, also on the part of men and papers representing the interests that call themselves pre-eminently conservative, pre-eminently cultured.

In such a struggle it is too often true that the feeling against those engaged in it becomes peculiarly bitter, not merely in the business houses of the great financiers who directly profit by the wrongdoing, but also in the clubs, in certain newspaper offices where business interests exercise an unhealthy control and, I regret to add, in other newspaper offices which like to be considered as in a marked degree the representatives of the cultivation and high social standing of the country.

Now, I do hope that you and your colleagues will treat all this bitterness with entire disregard. It is of small consequence to you, or to any of us who are engaged in this work, whether men think well or ill of us personally; but it is of very great consequence that we should do the work without flinching, on the one hand, and, on the other hand, without losing our good humored common sense, without becoming angered and irritated to a degree that will in any way cause us to lose our heads.

Therefore, I hope that you and Heney and your associates will keep reasonably good natured; but that above all things you will not lose heart. You must battle on valiantly, no matter what the biggest business men may say, no matter what the mob may say, no matter what may be said by that element which may be regarded as socially the highest element. You must steadfastly oppose those foolish or wicked men who would substitute class consciousness and loyalty to class interests, for loyalty to American citizenship as a whole, for loyalty to the immutable laws of righteousness, of just and fair dealing as between man and man.

It is just as bad to be ruled by a plutocracy as by a mob. It is profoundly un-American and, in a social sense, profoundly immoral, to stand for or against a given man, not because he is or is not a brave, upright, and able man, but because he does or does not belong to a labor union or does or does not represent the big business interests. In their essence, down at the foundation of things, the ties that are all-important are those that knit honest men, brave men, square dealing men, together, and it is a mighty poor substitute if we replace these ties by those that bind men together, whether they are good or bad, simply because they follow a particular business, have a given social standing, or belong to a particular organization. It is an evil and a dreadful thing for laboring men to endeavor to secure the political dominance of labor unions by conniving at crookedness or violence, by being 'loyal' to crooked labor leaders, for to be 'loyal' to the fancied interests of the unions when they are against the laws of morality and the interests of the whole people means ultimately the destruction of the unions themselves, as an incident to the destruction of all good citizenship.

But it is, if anything, an even more evil and dreadful thing to have the merchants, the business men, the captains of industry accessories to crime and shielders and supporters of criminals; it is an even more dreadful thing to see the power of men high in State politics, high in finance, high in the social life of the rich and fashionable, united to stifle the prosecution of offenders against civic integrity if these offenders happen to be their friends and associates; and most evil of all is it when we see crooks of a labor party in offensive and defensive alliance with the crooks of a corporation party. Labor unions and corporations alike should be heartily supported when they do good work, and fearlessly opposed when they stand for what is evil. The best kind of wage-worker, the best kind of laboring-man, must stand shoulder to shoulder with the best kind of professional man, with the best kind of business-man, in putting a stop to the undermining of civic decency, and this without any regard to whether it is a labor union or a corporation which is undermining it, without any regard to whether the offender is a rich man or a poor man.

Indeed, if there can be any degree in the contemptuous abhorrence with which right-thinking citizens should regard corruption, it must be felt in its most extreme form for the so-called 'best citizens,' the men high in business and social life, who, by backing up or by preventing the punishment of wealthy criminals, set the seal of their approval on crime and give honor to rich felons. The most powerful ally of lawlessness and mob violence is the man, whoever he may be, politician or business-man, judge or lawyer, capitalist or editor, who in any way or shape works so as to shield wealthy and powerful wrong-doers from the consequences of their misconduct.

You have heart-breaking difficulties with which to contend. You have to fight not only the banded powers of evil, but, alas, that it should be said, the supineness and indifference of many good men on whose zealous support you had a right to feel that you could rely. Do not be discouraged: do not flinch. You are in a fight for plain decency, for the plain democracy of the plain people, who believe in honesty and in fair dealing as between man and man. Do not become disheartened. Keep up the fight.

Very sincerely yours,

THEODORE ROOSEVELT.

Rudolph Spreckels, Esq.,
San Francisco, California.

Personal.

F. L. RANSOME is at Goldfield.

C. M. FUELLER has been in Nevada.

C. S. HERZIG is examining mines in Spain.

F. W. OLDFIELD is at Jamestown, California.

C. W. GOODALE leaves this week for Goldfield.

WALTER NEAL has returned to El Oro, Mexico.

MARK L. REQUA will arrive in San Francisco on June 29.

CHAS. G. YALE has returned from Jamestown, California.

F. N. FLETCHER has removed from Goldfield to Reno, Nevada.

J. H. CURLE is on his way home from Valparaiso, Chile, to London.

ARNOLD BECKER has gone to Nevada county, California, on professional business.

H. N. O. SPICER has returned from a professional trip in Mexico, to Denver, Colorado.

R. L. LLOYD, of the American Smelting & Refining Co., has left Salt Lake for New York.

R. T. WALKER is in Arizona, making investigations in various mines for the U. S. Geological Survey.

H. E. WEST, for the past two years engineer to the Spassky Copper Mine, Ltd., is returning to London.

ALBERT BURCH has returned to San Francisco from the McCracken Hill mines, Mohave county, Arizona.

JAMES DOUGLAS sailed from New York on June 17 for Europe. He will be absent about two months.

HENRY M. ADKINSON, formerly with the New England Co., of Bingham, Utah, is now at Telluride, Colorado.

R. B. WEDDLE has left Manhattan, Nevada, and will go at once to examine mines in Honduras and Nicaragua.

FRANCIS A. THOMSON has gone to Nevada, where he will be engaged in professional work for several months.

S. E. BRETHERTON, general manager for the Great Western Gold Co., Ingot, California, is at present in San Francisco.

F. S. SHEWELL has left Great Falls, Montana, and will erect a cyanide plant at the Phoenix mine, Cave Creek, Arizona.

WILLIAM KENT has resigned his position of Dean and Professor of Mechanical Engineering in the College of Applied Science of Syracuse University.

THOMAS T. READ, of the Imperial Pei-Yang University at Tientsin, has gone for an extended trip into the interior of China, which may take him to the border of Tibet.

F. LYNWOOD GARRISON will sail on June 27 for Colombia, accompanied by his assistant, WM. F. WARD. They will proceed from Colombia to Bolivia in October, returning to the United States in December.

ENGINEERING SOCIETIES.

The American Institute of Mining Engineers announces the 95th meeting to be held at Birmingham, Alabama, beginning September 29. Special excursions have been arranged to Chattanooga and Ducktown.

The Mining & Metallurgical Society of America has issued its Bulletin No. 1, bearing date of June 1, containing the list of officers and members of the society, the constitution, by-laws, and an announcement of the purposes of the organization as determined by the council. Fifteen districts have been set apart in the United States within which local sections will be established for mutual intercourse between the members. A general statement of intention to fix standards in engineering practice is set forth, and it is further announced that the society will discuss "questions relating to professional practice and ethics, with a view to the gradual formulation of rules for guidance, determined by the consensus of opinion in the Society." Bulletins will be issued monthly in future.

General Mining News.

ARIZONA.

COCHISE COUNTY.

(Special Correspondence).—The preparations at the mines of the Copper Queen Co., for the new system of handling the ore, are rapidly nearing completion. The last haulage drift is connected; the heavy rails are down in nearly all of the important drifts, and the trolley wire is strung. The cutting of all but one of the ore-pockets at the Sacramento shaft is completed. On the surface, at the Sacramento, the hoist is complete, with the exception of the steam connections. Two back braces are being added to the steel head-frame. The circulating-pumps are installed, and the cooling tower is under construction. All the steel framework over the railroad tracks for the car-loading system is erected, and much of the work for the final installation of the conveyor-belts is complete. There has been very little change in the regular mine work during the last few weeks. The ore-production remains practically the same. There have been a number of new ore discoveries, but none of marked importance. The Uncle Sam shaft has reached a depth of 610 ft. and is still being sunk. The Lowell shaft is 1447 ft. deep, and a station is being cut on the 1400-ft. level. Shipping of low-grade sulphide to the Old Dominion smelter, at Globe, has been resumed.——The Calumet & Arizona-Superior & Pittsburg production is again over 1500 tons per day, of which about 875 tons is from the C. & A. mines and 625 from the S. & P. mines. The copper output at the smelter for the month of June will be more than 4,000,000 lb. ——The No. 8 cross-cut, on the 1300-ft. level of the Hoatson, an S. & P. mine, has been run 500 ft. south from the station, and there is still 600 ft. to go to reach the south end of the claim. The No. 12 cross-cut, on the same level, has passed through about 60 ft. of good sulphide ore.——On the 600-ft. level of the Shattuck & Arizona a good body of 7% oxide and carbonate ore has recently been struck. This new body is a good smelting ore, being high in iron. Nothing definite has been given out as to the erection of a smelting plant at Douglas, but it is believed that preliminary work will be commenced during the next three months.——A recent discovery of lead-silver ore near the centre of the Warren claim of the Wolverine & Arizona, is taken as an excellent indication of future copper developments. The Warren claim adjoins both the Shattuck and the Queen properties, and in another part of the claim a good body of copper ore has been developed during the last few months.

Bisbee, June 20.

The Grand Arizona Copper Co. has shipped a quantity of tools and supplies to its property, near Douglas, and expects to start development work at once.——A rich strike is reported by Adams & Strand in the Gunnison hills, five miles from Dragoon. The vein is about 8 in. wide and assays over $300 in gold, silver, and lead.

GRAHAM COUNTY.

Operations have been temporarily suspended at the Polaris property on account of some trouble with the business affairs of the Southwestern Development & Improvement Co.——The New England & Clifton Copper Co. has started its new compressor, and will soon have the hoist running. A campaign of extensive development is to be undertaken at the Antietam mine, and with the Copper King, above Clifton, shipping regularly, the affairs of the company seem to be in good shape.

MOHAVE COUNTY.

The Stewart Warner Co., of Goldfield, has purchased all the mines on Music Mtn., and is doing preliminary work of establishing a camp in that locality. The district is 22 miles north of Hackberry, and is connected with the railroad by a good wagon road.——The freight rate on ores from Chloride and Kingman to the smelter at El Paso has been materially reduced.——The C. O. D. Mining Co. has been re-organized and John Boyle, Jr., has been elected president. The new management will proceed with development along new lines.——Tracy & Carrow have disposed of their interests in mines near the old Fay property to Los Angeles men. Work is to be begun on the mines at once.

SANTA CRUZ COUNTY.

The American, 10 miles east of Patagonia, has started work, and three shifts are at work sinking the shaft deeper. The American has not been worked for 20 years. A new shaft is now down 90 ft. and will be sunk 60 ft. deeper.

YAVAPAI COUNTY.

(Special Correspondence.)—The Arizona Power Co. expects to start construction on its power-house within the next month. The plant is about 50 miles east of Prescott, on the Verde river. The water is brought through seven miles of conduits, from springs on Fossil creek and reaches the power-house under a head of 1050 ft. Doble impulse-wheels, and General Electric Co., 3-phase, 60-cycle generators will be used. The power will be transmitted at a pressure of 45,000 volts to Jerome, Prescott, and Crown King, and will be used by the mines and the nearby towns. The United Verde Copper Co., of Jerome, has contracted with the power company for about 40% of the output. Twenty miles of wagon road have recently been constructed from Mayer to the site of the power-house. The construction will be pushed, and R. S. Masson, who is in charge of the work, is authority for the statement that the wheels will be turning early next year.

Prescott, June 23.

CALIFORNIA.

CALAVERAS COUNTY.

A discovery of yellow ochre is reported from the Jumper mine, near Mokelumne Hill.——The Woods mill, at Melones, is now running a 100-ton mill-test on ore from the South Carolina mine. The new company has decided to erect a 10-stamp mill, the capacity of which will be doubled later.

MODOC COUNTY.

The Sunshine & Rainstorm group, in the Hogue district, has been sold to Bassler & Schane, of Georgetown, Colo. A cash payment of $4000 was made, and two shifts have already started work. A new hoist has been ordered.

NEVADA COUNTY.

(Special Correspondence).—It is reported that Louis Rosenfield of San Francisco will resume active operations at the Inkmarque mine.——A winze is being sunk from the 500-ft. level at the Idaho-Maryland, and the 700-ft. level put in condition for active operations. A drift will be run from the 700-ft. level to intersect the vein.——It is reported that financial arrangements have been completed for the early resumption of work on the Ironclad mine. It is planned to install an ample plant of machinery. E. S. Black is superintendent.——Local people are actively pushing work on the Lily property, situated near the Idaho-Maryland mine. Some good ore has been opened up.—Charles A. Marriner and associates have acquired a bond on the Grey Eagle mine and will immediately put 20 men at work on the property. At a recent meeting of the Zeibright M. Co. the old board of directors was re-elected. Developments are being pushed steadily at the property.——The new 5-stamp mill at the Hotwater claim, above Graniteville, has been practically completed. A small force is developing a good vein of quartz.——Dividend No. 2, of $5000, has been declared by the Delhi M. Co. A good surplus remains in the treasury.

Grass Valley, June 22.

SHASTA COUNTY.

The Brackett mine, which has been lying idle for the past month, has been re-bonded and extensive work begun. The mine was taken under bond by H. O. Cummins about a year ago, and re-bonded to a Minneapolis company, which commenced a long lower adit to strike the orebody about 200 ft. below E. W. Brackett's old workings. A gasoline engine and a blower have been installed, three shifts of miners put to work, and the lower adit is now going in at

the rate of over two feet per day.——Furnace No. 1 of the Monmouth smelter, at Kennett, has been entirely re-built and is now running. This is the first time in the history of the smelter that all five furnaces have been in operation at the same time.

SIERRA COUNTY.

The Forest City Mining Co., operating the Mabel Mertz mine, six miles east of Forest City, is pushing its main adit ahead with two shifts, and it is expected that the gravel channel will be struck within the next 30 days.——W. O. Frost has taken an option on some quartz claims at the old town of Kanaka City, owned by John F. Owens, of Forest. Mr. Frost has men at work clearing out the old adit on the claims, and intends to sink on the vein.——F. P. Roddy and associates, from San Francisco, have obtained a year's lease on the Grizzly Con., formerly known as the Poker Flat vein, between Poker Flat and Grizzly. They intend to make a 60-days practical test of the ore, and have sent men to commence work.——The Alaska mine, at Pike City, has recently installed two new transformers, a centrifugal pump, and new pipe-lines. Sinking on the new vertical shaft will soon be resumed and driving will not be started until it reaches a point below the old workings.

TUOLUMNE COUNTY.

A tunnel is being built in the Nonpareil, at Big Oak Flat, for the purpose of connecting for rock-breaker and the mill.——Operations have been resumed at the mine on the Major ranch.——It is reported that five additional stamps will be added to the mill at the El Oro mine.——The Riverside may add 10 stamps to its mill and install a cyanide plant.

COLORADO.

CLEAR CREEK COUNTY.

(Special Correspondence).—A 4-in. streak of 600-oz. silver-lead ore has been uncovered on the Wolverine mine, Democrat Mtn. Operations are being carried on through the upper Sunburst adit, at a point where the Astor and the Wolverine join. Driving is now under way and after opening the ground for 15 ft. the streak has been found to be continuous. From the ground in close proximity a heavy production was made a few years ago.——F. Winters has taken a lease on a vein cut through the Sidney adit, and has started stoping on a streak of 70-oz. silver ore, that is from 14 to 20 in. wide. Shipments are to be started next week.——Criley Bros., leasing on the Barmettler property on Ute creek, have struck a 10-in. streak of ore that assays from 1 to 1½ oz. gold and 22 oz. silver. The initial shipment was made this week consisting of about two tons. A solid streak of smelting ore 10 in. wide has been encountered in the west drift being run on the Gametta vein cut by the Joplin adit. The ore carries 65% lead, 2 oz. gold, and 97 oz. silver per ton. It was the intention of Manager B. J. O'Connell to start a raise as soon as the drift reached a point under the shaft workings, but so great did the improvement become that he decided that time would be saved by proving the extent of the discovery. Shipments are to be started at an early date.——F. A. Maxwell, lessee of the Colorado Central, has started a shipment of 1000 tons of lead-zinc ore to the Linn Consolidated mill. This ore will be treated for testing purposes, while the machinery is being adjusted. The Linn Co. tramway is not yet completed, and as the concentrator was ready to put into commission it was decided to treat this ore for Mr. Maxwell. In the event that the expected saving of the metals is effected, Mr. Maxwell will erect a similar plant. This ore is being taken from the Sleepy drift, run from the Equator adit.——A shipment of 18 tons of smelting ore was made last week from the Capital mines and a settlement of $5500 net was received, or at the rate of $305.50 per ton. This is the most remarkable body of ore ever uncovered in the history of mining in the Georgetown district. The streak of smelting ore is from 4 to 7 ft. wide in the west drift on the Aetna vein, while in the centre there is a break where about 4-in. rock appears. At no time during the history of mining in this district has such a large body of ore been uncovered at the same depth, operations being carried on 1700 ft. from surface. Alongside of the smelting ore is to be found from 7 to 10 ft. of concentrating ore.——It is evident that the Seven-Thirty vein has been lost in the raise to drain the shaft workings. This raise is now nearly 50 ft. above the bottom, and engineers state that it will be necessary to continue it to the level above, or else run cross-cuts to strike the vein. The men are at work 5600 ft. from daylight and great fear is manifest over their safety in case water should break through. However, 150 ft. of fuse is being used in shooting, giving the miners ample time to make their escape.——A big force of men is being employed by the Red Oak M. & M. Co., operating the Sunburst-Astor group of mines, Democrat Mtn. The old adits are being re-timbered and placed in condition to permit of the exploitation of a large area of virgin ground. On the Astor, which was never worked to a depth exceeding 240 ft. a shaft is to be sunk for another 100 ft. for the proving of the continuity of the ore-shoots. The upper adit on the Sunburst is to be extended several hundred feet also.——A syndicate of Denver men has secured an option on the Pulaski mine, situated on Leavenworth Mtn. The old workings are now undergoing an expert examination, while tests are to be made of the dump. The Pulaski vein was intersected by the Hall adit a number of years ago, a big body of medium grade ore having been uncovered. As the men financing that cross-cut did not own the vein no attempt was made to determine the extent of the discovery. However, now that the Hall bore is to be driven on into the hill, property intersected by it has come in great demand. The new company will operate from a tollage basis, as well as on its own account. B. J. O'Connell, of Georgetown, who has been appointed manager, states that a powerful compressor-plant will shortly be installed.——An energetic campaign of development has been started upon the Star group of claims in the Peru district. Arrangements have been perfected whereby operations are to be carried on through the Revenue adit. This company will also drive the Calla adit an extra 200 ft. to cut the vein 175 ft. under the deepest workings of the Revenue. John O'Dea has secured a lease on a block of ground and is running a drift on a streak of ore from 5 to 8 in. wide that mills as high as 3 oz. gold and 275 oz. silver per ton.——The Mendota mill, situated below the portal of the Victoria adit, is now treating exclusively dump matter carrying silver, lead, zinc, and iron. For the last three months Stephens Bros., the owners, have been netting $1200 per month, despite the low price of the metals. The mill now has a capacity of 60 tons per day, a number of improvements having been made.——A force of men has been sent to the Mineral Chief mine, Democrat Mtn., to place the workings in condition for the delivery of ore over the aerial tramway to the Linn Con. mill. This tramway will be in readiness to start within a couple of weeks.——H. Davenport has taken a lease on the sixth level of the Gold Dirt, Covode Mtn. Stoping has been started upon a streak of ore which is 18 in. wide, and assays $40 per ton in gold and copper. A. Thoman, leasing on the same level, is extracting a heavy tonnage of high-grade ore, one carload of $80 smelting ore being shipped each week.

Georgetown, June 22.

GILPIN COUNTY.

The Gilpin-Eldora Mining Co., owning the Eldora mine, near Central City, is planning to resume work within 30 days.——Two carloads of machinery for the Evergreen mill, in the Pine Creek district, were received at Black Hawk during the past week, which have since been hauled out to the new mill and will be installed at once.——The Black Hills & Denver Gold Mining Co. decided, at a recent stockholders' meeting, to resume work at its property in Boulder Park.

LAKE COUNTY.

Some improvements are being made on the Cleveland property, near Stumptown, which include the removal of a

portion of the old dump, so that it will not interfere with the working through the shaft. The men who were employed underground are now engaged in this work.——Rich ore is reported from the Hahnewald lease, on the No. 4 shaft of the Ibex, at a depth of about 1000 ft. The streak is not more than one inch wide, but it is claimed that it assays $125 per pound.

SAN JUAN COUNTY.

A fire at the Gold King mine, at Gladstone, destroyed all the buildings at the mouth of the adit, and did considerable damage to the tramway. Three miners, who were in the workings at the time, were overcome by gases accumulating in the workings, due to the closing of the doors of the adit. A rescue party was organized, and were successful in bringing out two of the men alive, but five of the party themselves were killed by the fumes.

TELLER COUNTY.

The newly constructed mill at Gillett started operations last week. The mill has been practically rebuilt by the lessees, who are to treat the old Kimball dumps, which average only $5 to $6 per ton in gold.——It is possible that the property of the Pinnacle Gold Mining Co., on the northern slope of Bull hill, may be worked in the future. An examination is being made by Cripple Creek men in the interest of a leasing company.

IDAHO.

SHOSHONE COUNTY.

(Special Correspondence.)—A feature of the mining industry all through the Coeur d'Alene this season is the immense quantity of machinery which has already been delivered or ordered for both the larger mines and the prospects. There is no way of gauging the amount that must have been spent in this direction since the beginning of the year, but railroad men state that there has been nothing like the past few months in the history of the country. This machinery consists for the most part of compressors and hoisting apparatus and even an occasional mill. Up to the present time the district has offered a splendid harvest for the different manufacturers and the prospects are that the demand will be increased rather than diminished throughout the summer. Enormous sums have already been expended in new equipment by the Hercules, the Hecla, and other big properties, and here and there arises talk of small stamp-mills for the outlying gold-quartz properties. Nearly 5 ft. of pure galena has been cut at a depth of 800 ft. in Bear Top mine, and further prospecting is increasing the value of the orebody, the full extent of which has not yet been determined. A slight fault was encountered, as in the upper workings, but after further driving of about 30 ft., 5 ft. of galena was opened up on the foot-wall. Since this the men have driven 12 ft. toward the hanging wall, which has not yet been encountered, while the adit shows high-class concentrating ore all the way.

Practically all the big mining companies of the district have now filed their annual statements with the county assessor, and according to these documents 1,366,076 tons of lead-silver ore have been shipped from the district during the year 1907, netting operators in Shoshone county a gross profit of $14,367,418, and a net profit of $4,810,522. While these figures are not quite up to the standard of 1906, owing to the depression in the metal markets, it is nevertheless gratifying to note that the number of shippers is steadily increasing, and even at lower prices there is but little doubt that the present year's production will exceed that of any year in the previous history of the county. The net profits of nearly all the big companies show a substantial decrease, for the reasons stated. The statement issued by the Federal Mining & Smelting Co. shows that the profits for 1907 fall short by over one million dollars from the record of 1906. In 1907 the four mines of this company extracted 800,200 tons of ore, of a gross value of $6,185,477, as compared with 933,577 tons extracted in 1906, of a gross value of $7,775,770, while the net profits for the two years respectively amounted to $1,588,707 and $2,685,212, and this in spite of the fact that the working expenses of the mines for 1906 were considerably higher than those for 1907. The accompanying table is a summary of the returns made to county assessors by the principal mines of the Coeur d'Alene for the year 1907.

Wallace, June 23.

(Special Correspondence.)—Some rich samples of pure galena ore from Bear Top mine, near Murray, have been on display at Wallace. The ore was encountered 800 ft. below out-croppings and is thought to prove the depth and permanence of Murray lead-silver veins. The rich ore was discovered along the foot-wall of the vein, and after driving 15 ft. still shows its original width of 4 ft. and shows no signs of diminishing. The vein is about 20 ft. wide at this point. The ore assays 30% lead and some copper.——A long cross-cut adit is to be run on the famous Copper King property, near Mullan, according to a decision of the owners at a recent stockholders' meeting. Work will begin in 30 days and continue till ore is opened on that level. The property is already well developed and was under bond to the Greenoughs when the copper flurry cut short the deal last fall. It contains large bodies of low-grade copper.——The Morning mill is now in operation with three shifts only one side, however, having been started. The other side will be started shortly, and shipments are expected to begin soon. Men are being constantly hired for the mine.

Wardner, June 20.

RETURNS FROM OPERATION OF THE COEUR D'ALENE MINES DURING 1907.

Name of Company.	Tons Extracted.	Gross Value.	Cost of Extraction.	Cost of Transportation, Reduction and Sale.	Value Improvements During 1907.	Net Profit.	Net Loss.

MICHIGAN.

The Adventure has suspended all mining operations and are exploring with two diamond-drills. It is rumored that the stamp-mill will be sold.——The Cliff working shaft is nearly unwatered to the eighth level. Three drills are being operated, all of which are driving. The connection between the third-level drift and the old shaft, abandoned

30 years ago, should be completed by July. Twenty-five men are employed underground and the rock broken in development work is of a promising grade.——The Keweenaw Central passenger train ran into Calumet last week for the first time.——The completion of the cross-cut between No. 1 and 2 shafts of the Tamarack this week at a depth of 900 ft. will help solve the water problem at that mine. The cross-cut between the two shafts, at a depth of 550 ft., will be completed later this month. With both cross-cuts in use, Tamarack will be in excellent shape. No. 1 shaft is to be used only for hoisting water. At present Tamarack is handling a small amount of rock for the Ahmeek. Less than 30% of the Ahmeek tonnage goes to the Tamarack mill. It is only a question of a short time before the Tamarack will find it desirable to use even this tonnage at its mill for its own shipments. This will necessitate the Ahmeek shipping entirely to the Osceola mill, or, what is considered more likely, to the Isle Royale stamp-mill.——The Mohawk last week declared a dividend of $2.50 per share, payable July 10.

MONTANA.

French, Morse & Bassette have given a lease and bond on their mining property near Argenta to the Goldstone Mining Co. It is announced that the company is prepared to spend $50,000 in development work and installation of machinery. A large stamp-mill will be erected.——The Strawberry mine, near Pony, has just made its first shipment of concentrates to the East Helena smelter.——Stations have been cut at the 20th and 22nd levels of the North Butte, where everything is now in readiness for the starting of cross-cuts to the Edith May and Jessie veins. The Edith May vein at these depths is distant less than 100 ft. from the shaft, and should accordingly be intercepted in a month or two.——The new smelting contract of the North Butte with the Washoe smelters became effective June 1. By the terms of the contract, smelting costs are reduced about 50c. per ton, a very material saving on a daily output of more than 1200 tons.

NEVADA.

ESMERALDA COUNTY.

It is reported that the construction of a new 50-ton mill for the Rawhide Mining Co. will be started not later than July 1. The mill is to be built south of Rawhide, midway between the source of water and the Last Chance claim.——J. D. Hubbard and others have purchased the A. & M. group of 10 claims, seven miles from Hawthorne, on the Bodie road. A cash payment of $40,000 was made.——The Gem Florence lease, on the Florence ground, has secured an extension of six months, and an increase in the area of the holding. Work will be resumed and shipments again started. The lease is controlled by D. W. Smith and others, of Elmira, New York.——Satisfactory progress is reported at the Nevada Empress mill, at Gold Mountain. The machinery has been shipped and the building material is on the ground or at Cuprite. An aerial tram will probably be constructed.——It is reported that oil has been struck near Blair.——The mines of Goldfield produced, during the week ending June 19, a total of 2150 tons, valued at $178,940. The Tonopah mines produced 5895 tons, of an estimated value of $150,875.

HUMBOLDT COUNTY.

The Dun Glen mine, at Tiptop, is to ship its first car of ore soon.——The Tiptop Mine Owners' Association has adopted the Tonopah scale of wages, and the utmost harmony exists between owners and miners.

LANDER COUNTY.

The Dean mine, situated about 16 miles southeast of Battle Mountain, has resumed operations after a period of inactivity lasting since some time last year. A new 20-stamp mill is being considered, to take the place of the 10-stamp mill now in use.

LINCOLN COUNTY.

A rich strike is reported from the Duplex mine, at Searchlight. It is claimed the ore, which was uncovered on the 500-ft. level, will assay $15 per lb. in free gold.——The Esther group, three miles north of Searchlight, has been sold under lease and bond to the Central Trust Co. of Denver.——The Philadelphia shaft has reached a depth of 620 ft., and cross-cuts have been started both to the east and to the west.

NYE COUNTY.

Work has been resumed at the Quartette, on the south end of Ladd Mtn.——The machinery of the Homestake mill was run for the first time last Saturday, although continuous operation will not be started for a few days.——The Burner-Sweeny lease, at Telluride, claims to have uncovered some cinnabar ore at a depth of 35 ft.——Frank P. Davis and J. C. Humphrey have each taken a lease on a block of the Thelma ground, at Manhattan, and will start work at once.——J. B. Giffen, who was the first to use the dry-wash system at Manhattan, is installing a Westerfield machine on the Verde ground and a Curtis on the Golden Gate, on both of which properties he has leases. It is his intention to put two shifts at work on each machine at once, and as soon as everything is in running order, to work each to its full capacity. When three shifts are working, the two machines will handle 200 yards of dirt per day. The samples of the gravel assayed $1.40 per ton, and Mr. Giffen expects to save on an average of $1.25 per ton.——Arrangements have been completed for the erection of a 100-stamp mill at Walker lake to treat Rawhide ores. The treatment will be amalgamation, concentration, and cyanidation. The site will be about five miles below Schurz.——A discovery of great interest to the whole camp of Tonopah, and of undoubted value to the Belmont and other mines on the north of Mizpah hill, is the ore on the 1000-ft. level of the Belmont mine. Heretofore the veins encountered on the hill have been cut off on their easterly trend by the Mizpah fault and it was feared that no ore would be found north of this fault. The Belmont, however, has been doing extensive prospecting work on the main east cross-cut, and has gone through the fault and encountered a rich stringer of high-grade sulphide ore at least 50 ft. to the north of the fault.

WHITE PINE COUNTY.

The Ely Central has started an active campaign of development. A three-compartment shaft is to be sunk on the Weber claim, and two small shafts will be put down for prospecting purposes. Five men are now at work in the adit on the Intervention group.——H. A. Woodworth has purchased the Lucky Strike group of four claims, in the Hunter district. The consideration was $6500.

UTAH.

JUAB COUNTY.

The Gemini, better known as the Keystone, is installing two big electric pumps on the lower levels of the mine. This is taken to mean that deeper mining is planned by the company.——The lease given some time ago upon certain parts of the Bullock mine has expired, and it is the intention of the company to push development work on its own account. Two winzes will be sunk in the sulphide ore, one each in the north and south drifts. A raise will also be made on the orebody recently uncovered.——The Mammoth mine will be closed from July 1 to 10, in order that the machinery about the mine may be overhauled and repaired. It is expected that ore shipments will be resumed within the next 10 days, from the tonnage accumulated in the bins and on the dump.——Shipments of ore from the Tintic mines for the week ending June 20 were as follows: Bullion Beck, 3 carloads; Centennial Eureka, 39; Eureka Hill, 3; May Day, 5; Sioux Con., 1; Uncle Sam, 2; Tetro, 1; total, 54 carloads.

SALT LAKE COUNTY.

Jesse Knight, of Provo, has, with a number of friends, secured control of the old Emma mine at Alta, which in the '70s was sold to English capitalists for $5,000,000. The mine was a failure and caused an international scandal. Last year several Utah operators obtained the property from its English owners and began work, in the belief that its resources had not been exhausted. During the fall three

shipments of silver-lead ore were made, and a 2-ft. vein of the same ore is now being followed.

SUMMIT COUNTY.

Six men started work this week on the Giles Con. property, in Big Cottonwood district. It is reported that other mines in that neighborhood will also open soon.——The payroll of the Daly-West numbers 100 men at present, and will be increased as soon as the men can be used.

WASHINGTON.

FERRY COUNTY.

(Special Correspondence.)—The Copper Key reports a strike of copper sulphides, in a raise from the No. 2 adit. The company is now extending the No. 3 adit, in hopes of striking the same orebody. The Hercules, owned by J. T. O'Connell, of Republic, has struck galena and copper in its adit.——The drift running centrally through the first vein on the Grant Con. is reported to have struck higher-grade copper ore than it has been hitherto revealed. Work is to be continued steadily.——The first car of ore from the old Republic mine has been sent to the smelter. This mine, which was formerly active and treated a large amount of gold ore, has been idle for several years until a short time ago, when Richard Mulroy leased it and began operations.——J. L. Harper, manager of the Pearl Con. mine, at Republic, states that the property will be reopened again in a short time. Some Kentucky people who recently made an examination are expected to return this week and take hold of the mine. There is a large amount of development work done.

Republic, June 22.

OKANOGAN COUNTY.

(Special Correspondence).—The Ruby mine has been shut down during the absence of the manager, who has gone to eastern cities to secure funds for the establishment of a reduction plant. Seven carloads of ore were shipped to the Tacoma smelter during the spring, but owing to high freight this rate will not be continued.——A diamond-drill is now operating on the Kelsey properties, on Kruger Mtn.——The Nighthawk mine is installing a new concentrator which it is expected will be in operation in a few weeks.

Chesaw, June 15.

STEVENS COUNTY.

(Special Correspondence.)—The Eagle group of claims has been sold by the Eagle Con. Gold Mining Co. to the Blue Star Mining Co. for $13,000. Two other claims have also been purchased, which adjoin the United Copper. The adit will be extended from the Eagle to this vein, which is here 12 ft. wide. The lead-silver vein on the old Eagle group will be explored by a winze at the same time.——The United Copper is now shipping 40 tons of ore per day to the Northport smelter. Development work is in progress on the winze being sunk to the 900-ft. level.

Chewelah, June 13.

CANADA.

BRITISH COLUMBIA.

The shipments of ore from Granby mines, Phoenix, for the month of May were 93,316 tons, and with the exception of last March was the biggest monthly tonnage ever sent out from the mines. In March all the furnaces at the smelter were running at full capacity, while during May two furnaces were out of commission for a considerable length of time. The shipments for the first five months of 1908 total 294,317 tons, showing a big increase over the same months last year.——The Jumbo mine, at Rossland, has resumed operations.——The Oro Denoro mine of the B. C. Copper Co., in Summit camp, has been making a good showing in the shipping list since resuming a few weeks ago. Fifteen to 17 cars of ore are now being shipped daily to the company's smelter at Greenwood, and its shipments of 3270 tons last week are more than equal to its entire tonnage in 1907. Sixty men are now working in two shifts at the mine, and it is expected the tonnage will continue to increase.——The Big Bend mica mines, near Revelstoke, will begin operations soon. A crew of men has been sent in by way of Beaver.——It is reported from New York that the Britannia copper mines, on Howe sound, will be opened the latter part of this month.——The Phoenix M., S. & D. Co. has been organized to work the Woodburn mining property, in Wellington, three miles from Phoenix. The new company is receiving proposals for the driving of a 200-ft. adit, and other development will be started in the 600-ft. shaft now on the property. The ore is said to be rich in copper and gold.——The Bertha Mining Co., at Grand Forks, is to install a stamp-mill and gravity tram.

Following is the tonnage of ore shipped from and crushed at the mines of Rossland for the week ending June 13, and for the year to date:

Mines.	Week.	Year.
Centre Star	3,000	79,971
Le Roi	1,575	38,924
Le Roi No. 2	350	12,269
California-Giant	....	95
Blue Bird	....	110
Red Eagle	....	20
Evening Star	70	488
Total	4,995	131,887

There was received at the Consolidated Co.'s smelter, at Trail, during the past week, 4284 tons of ore. Besides that received from Rossland, shipments came from other mines as follows: Snowstorm, 603 tons; First Thought, 154; St. Eugene, 89; North Star, 23; Richmond Eureka, 45; Ymir, 22; Silver Cup, 31 tons.

ONTARIO.

Shipments from Cobalt for the week ending June 13, and since Jan. 1, in pounds, are as follows:

	Week June 13.	Since Jan. 1.
Buffalo	.....	653,710
Coniagas	63,100	568,680
Cobalt Lake	.....	246,455
Crown Reserve	.....	84,000
Cobalt Central	.....	56,380
City of Cobalt	.....	452,110
Drummond	.....	148,600
Foster	.....	238,400
Kerr Lake	57,980	462,300
King Edward	.....	127,240
La Rose	60,000	2,361,652
McKinley	123,600	1,497,160
Nipissing	.....	1,743,120
Nova Scotia	43,990	271,540
Nancy Helen	.....	140,420
O'Brien	276,330	2,817,300
Right of Way	61,050	303,290
Provincial	.....	143,210
Standard	.....	39,730
Silver Leaf	.....	196,620
Silver Cliff	.....	52,000
Silver Queen	.....	634,510
Townsite	.....	85,100
Tem. & Hudson Bay	65,000	664,000
Tretheway	67,600	1,065,050
Watts	.....	246,020
Little Nipissing	40,100	40,100
Totals	798,760	15,874,508

MEXICO.

The San Mateo Mining Co., Urnachi, Chih., has completed the 690-ft. adit to cut the vein, and rich silver-gold ore has been struck. The company is planning to put up a small water-jacket smelting furnace. T. A. Ripperdan is general manager.——A 20-stamp mill is to be erected on the Santa Catarina mine, at Santa Catarina, Oax.——A 75-ton stamp-mill is being built on La Mejia group of mines, near Saric, Son. It consists of six 150-lb. rapid-crushing stamps, with amalgamators and concentrators. This is an old property, developed to a depth of 240 ft., showing a width of vein of 85 ft., all of which is in silver-bearing quartz in porphyry.

Special Correspondence.

LONDON.

Botallack, Cornwall.—East Pool Developments.—Cornish Operations in Malay.—Tronoh Mine.—Briseis Tin, Tasmania.

One of the most interesting mines in Cornwall is the Botallack. In fact it is of romantic interest seeing that the shaft is on the cliff and the workings extend under the sea. After being closed down for many years it was re-opened by the Allen & Meyerstein group eighteen months or so ago. A great deal of money has been spent clearing and re-timbering the old levels and sinking a new main shaft. Also electrical machinery and producer-gas plant have been provided. Most of this work has been done by William Thomas. Recently he handed over the work to Captain W. R. Thomas, of Tywarnhaile, on his removal to Camborne to take up his duties as consulting engineer to the Allen & Meyerstein group. Forty head of stamps are being erected, twenty being already in position and ready to start. At first the material on the dump will be treated, but it will not be two months before ore is being brought up from the stopes. I hope before long to give a complete account of the mine and the new plant. Another event of considerable interest in connection with tin mining in Cornwall is the striking in the lower levels of an unusually strong vein at East Pool. This vein so far as at present developed is 6 ft. wide and contains 140 lb. of black tin per ton. The ore is remarkably clean and is free from wolfram and arsenic. In the upper levels of the mine the ore that is at present being worked is very complex, containing wolfram, arsenic, and copper. As the workings go lower the other metals disappear. It is found also that in depth the veins dip into the adjoining Agar mine, which belongs to the same company. The Agar property was acquired about twelve years ago, chiefly with the object of enabling the engineers to drain the lower levels of East Pool. As a mine, Agar has not been a success, and has to that extent been somewhat of a clog on the company, though indirectly from the drainage point of view the expenditure has been worth while. Now that the rich East Pool veins are dipping into it, Agar may yet come into prominence as a mine. It is of interest at this juncture to mention that the company at present in control has been working East Pool on the cost-book plan since 1834. There are 6400 shares on which £4 13s. 3d. has been paid up. The total distribution per share to date has been £74 16s. 6d. There is an inclination in some quarters to find fault with the cost-book system, because proper provision for reserve funds and funds for extension of plant is never made. East Pool is an example to the contrary, for very large sums have been spent out of revenue for the purpose of re-organizing plant and extending operations. The present discovery of such rich ore is most welcome. It must be remembered that the content is more than three times that of the ore now worked at Dolcoath.

A good deal of Cornish money is employed in operating tin mines in other parts of the world, especially in Malay and the East Indies. It may seem odd that the money should be used thus instead of in re-opening the old mines. The reason for all this is a long story. When the Malay production became so large 30 years ago the reaction in the market for tin hit the Cornishmen seriously. The Eastern deposits are mostly gravel and are worked by cheap labor. Against these conditions deep Cornish mines could not compete. To get some of their money back, Cornishmen took up Malay properties. I believe that at the present time more new Cornish capital goes to Malay than to the local mines. For some reason it is the fashion for James Wickett, the stockbroker of Redruth, to advise his clients to go into Eastern gravel mines, and the Cornish smelters, the Lanyons, Bains, Pearces, and Bolithos, follow him. One of the most interesting of the Malay companies is the Tronoh. The shares in this company are held about equally in England and in the East. It was formed in 1901 with a capital of £160,000. Dividends have been paid amounting in all to 150% so far. The output has averaged about 2000 tons of tin concentrate per year. During the last year or so the production has become rather less for one reason or another, chiefly because the method of underground mining adopted is not now suited to the condition of the deposit. It has been decided to make a change, and in future to work open-cast. For this purpose a good deal of new capital-expenditure will be required. It has been found impossible to issue new shares in the existing state of the money market, so the profits for the whole of this year are to be allocated for the purpose. Gilbert Pearce, head of the tin smelting works of Williams, Harvey & Co. and brother of Dr. Richard Pearce, is the chairman of the Tronoh company.

It is appropriate to mention the Briseis tin mine in Tasmania, about 30 miles northeast of Scottsdale. This company was floated in 1899 by the Venture Corporation. At the time there was considerable criticism with regard to the high price paid in relation to the nature of the deposit. In 1903 the company's engineers, Lake & Currie, found the

limits of the deposit, and since then no further discovery has been made. At the present rate of working the deposit will be exhausted in about a year. The company also owns a 58% interest in the adjoining New Brothers' Home property and also owns the Ringarooma property. The first named is a good producer, but the latter has not yet been proved. During 1907, the amount of gravel treated at Briseis was 449,400 cu. yd., and the yield 1017 tons of concentrate. At the New Brothers' Home 215,200 cu. yd. yielded 396 tons, of which 52% went to the Briseis company. The total metallic output of the Briseis and its proportion from the New Brothers' Home was 910 tons, which sold for £151,222. These figures compare with 912 tons and £168,123 during 1906. The profit for 1907 was £109,219, and £90,000 was distributed as dividend. It was not until 1906 that dividends were paid, and in that year £112,500 was distributed. With only another year or so of life before it there is not much chance of the capital being returned. The issued capital is £600,000, of which £190,000 in cash and £320,000 in fully paid shares went to the vendors, the Venture Corporation. Events have justified previous criticism relative to over-capitalization in this instance.

It was known as early as 1900 that the original valuation of the gravel had been grossly over-estimated, but profits could have been made had not unnecessary equipment, not warranted by the extent of workable ground, been installed. We speak of the costly water-way constructed to bring water to the mine.

ROSSLAND, BRITISH COLUMBIA.

Lead Bounties, Past and Present Effects.—Granby Dividend.—Ore Discoveries in the Josie.

The most important piece of news received in this district during the past couple of weeks, is the information that the bounty on lead mined in Canada, which was to cease on June 30, is to be continued for another period of five years. The sum set aside for the payment of this bounty five years ago was $2,500,000, of which only $700,000 has been used. This was a strong factor in favor of the extension of the term. This grant is for a bounty of $15 per ton on lead mined and smelted in Canada when the price of that commodity is ruling at £12 10s. on the London market, or when the selling price is under that figure. When the price of lead rises above £12 10s. then the bounty begins to decrease until, if the price of the heavy metal should rise high enough, the bounty would entirely cease. This condition actually existed when lead was at its highest figure a year or so ago. One of the features embodied in the new term of the grant is that instead of the bounty beginning to decrease when the price of lead reaches £12 10s. it will begin to be reduced when the figure is £14 10s. This is a point that the lead miners have placed great stress upon, because owing to the condition of the lead mining industry in the Slocan at the present time, having to contend with a recalcitrant lead-zinc ore and other difficulties, including lack of adequate transportation facilities, the miners feel that they must have a stable minimum price behind them in order that they may operate their mines and develop this portion of the mining industry of British Columbia without losing money. There is no doubt whatever but this bounty during the last few years has been a stimulus to lead mining in the Slocan. Many small prospects, with showings of high-grade ore, that are now shipping and in a fair way to become large mines, would be still closed down but for the bounty. The big mines have found it of great assistance, especially when the price of lead was low and the cost of mining high. Another point in the new arrangement is that the amount of bounty to be paid during any one year will not be limited to $500,000, as heretofore. This will tend to stimulate production should the mines produce a big tonnage in any year while the bounty is in existence. The beneficial effect can be realized when it is stated that for the year 1904, 12 months after the grant had been made, the lead produced in British Columbia amounted to 36,646,244 lb., valued at $1,421,874, while for the year 1907, which was even lighter than 1906, the lead produced was 47,738,703 lb., valued at $2,291,458, an increase of 11,092,459 lb. An industry of this magnitude is worth fostering, especially when it may be said to be still in its infancy. The total amount of lead produced in British Columbia alone, from the time when the Hudson's Bay Co.'s trappers dug it up for bullets, to the end of 1907, is estimated to be worth about $19,917,197.

Great advances have been made in Canada during the last few years in the manufacturing of lead pipe and other forms of useful articles. As the demand is growing throughout the country and as there is a tendency toward stronger tariff protection there will no doubt be a time in the near future when the lead mines of the country will be paying the Government a bigger bounty than the lead-miners are receiving today.

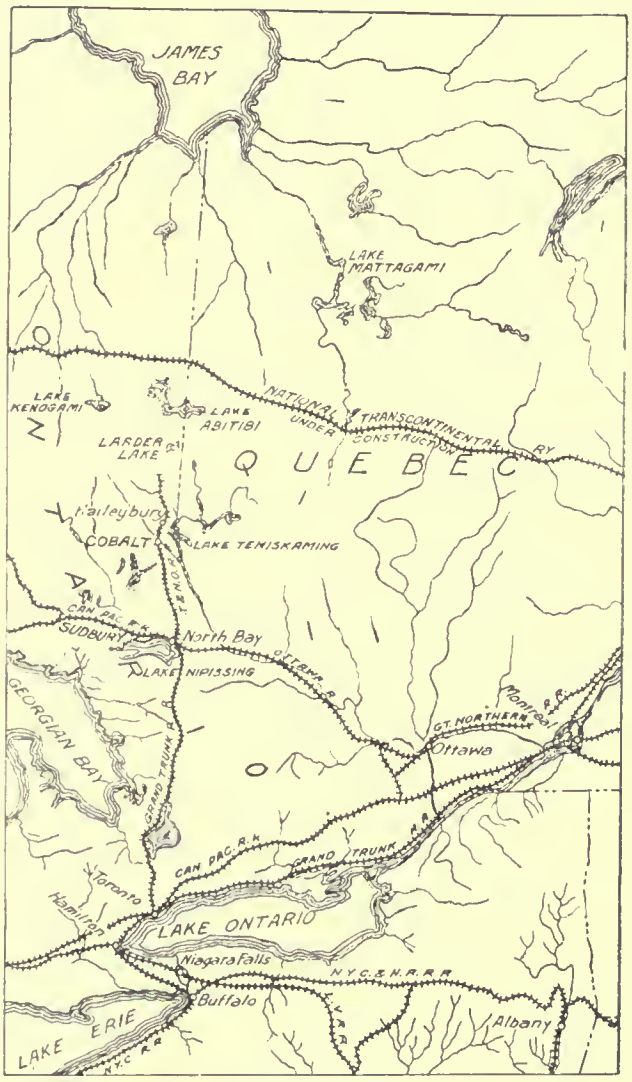
The report that the Granby Co. had declared a dividend of 2% on the par value of its issued stock came as a mild surprise to mining men interested in this district. There has been much discussion as to whether it was paying the Boundary mines to operate under existing conditions and the declaration of this dividend settles the knockers.

Excellent ore is now being taken from the lower levels of the mines in Rosland camp. Last month from a lode that averaged 2 ft. wide, in the Josie mine of the Le Roi No. 2, Ltd., assays were obtained of 3.77 oz. gold and 6.7% copper, or $88 ore. Another vein that averaged 4 ft. 1 in., carried 2.82 oz. gold and 9.7% copper, equal to $79 per ton. While these bodies of ore, which are high-grade for this camp, have been running small in the Josie, yet the rich gold-bearing ore found in the lower levels of the Le Roi and Centre Star-War Eagle mines has been uncovered in larger bodies.

TORONTO, CANADA.

Florence Mining Co. v. Cobalt Lake Mining Co.—Little Nipissing Begins Shipment.—Chambers-Ferland Sold.—Ore Shipments.—Crystal Mine, Wahnapitae.—Moose Mtn. Iron Mines.

The long-standing action of the Florence Mining Co. against the Cobalt Lake Mining Co. to set aside the patent granted to the latter company by the Ontario Government for $1,085,000, and to establish the claim of the plaintiffs



Map Showing Position of Cobalt and New Districts in Ontario.

on the ground of original discovery, was tried in Toronto before Judge Riddell last week. The facts of the case have been previously given, but the more important points may be briefly recapitulated. W. J. Green, who afterward assigned his claim to the Florence company, made a valuable discovery in 1906. He applied to have his claim recorded, but this was refused on the ground that the property was not open to prospectors, as an order had been issued in August, 1905, withdrawing Cobalt Lake. It was claimed on behalf of the Florence company that this order had been rescinded, as shortly afterward another order was issued withdrawing Coleman township, which was followed by a final order again throwing open Coleman township. As Cobalt Lake is situated within the township, it was contended that under this last order, it was also open, and maps issued about this time to prospectors showing the territory available for discovery confirmed

this view. However, the Government refused to recognize the claim, sold the property to the Cobalt Lake Co., and when the Florence Co. took the case to the courts, procured the passage of a special act validating the title of the holders. The legal proceedings were stayed until it was seen whether the Dominion Government would exercise its powers of disallowance and set aside the act. This it refused to do, and as a consequence, the action of the Florence Co. has been dismissed solely on the ground that the Legislature has absolutely unrestricted powers in the matter. On this point Judge Riddell was emphatic, while clearly indicating his opinion as to the confiscatory character of the legislation. In his decision rendered on June 15 dismissing the action with costs, he said: "The Legislature, within its jurisdiction, can do everything that is not naturally impossible, and is restrained by no rule, human or divine. If it be that the plaintiffs acquired any rights, which I am far from finding, the Legislature had the power to take them away. The prohibition 'thou shalt not steal' has no legal force upon the sovereign body, and there would be no necessity for compensation to be given." The counsel for the Florence Co. has intimated that an appeal will be taken and the case carried, if necessary, to the Imperial Privy Council. They are hardly likely to get a reversal of the decision, as Judge Riddell's interpretation of the law is in line with Blackstone's famous dictum: "The Parliament of England can do anything except make a man a woman, or a woman a man."

Heavy shipments of ore are being made from the Cobalt camp, the list of shipping mines being increased last week by the addition of the Little Nipissing, which sent a car of ore to Copper Cliff, taken from the property recently leased from the Peterson Lake Co. The shaft is down 50 ft. and the vein 5 in. wide is proving very rich. The Chambers-Ferland property in the heart of the ore-producing district, adjoining the La Rose, O'Brien, and Nipissing, has been secured by Montreal and Toronto interests and a company is being organized to operate it under the name of the Chambers-Ferland Mining Co., Ltd., capitalized at $2,500,000, the stock of which will shortly be put on the market. Two shafts are being put down, in both of which high-grade ore is encountered. The ownership of the property was for a long time in dispute, but finally a clear title was secured from the Government by an agreement to pay a royalty of 25% on the output. The Amalgamated property lying west of the Tretheway has been leased by Manager Madden, of the Little Nipissing.

The Crystal gold mine, at Wahnapitae in the Sudbury district, has been sold by Patrick Shannon, of Pembroke, Ontario, to a Toronto syndicate, including John T. Ryan, Stafford Higgins, and Gordon C. Jennings, Mr. Shannon retaining an interest. The mine was worked three years by a syndicate and considerable development work done, one shaft being sunk by hand-drilling to 185 ft. Transportation difficulties and the expense of introducing machinery caused the temporary abandonment of the enterprise, Mr. Shannon finally buying out his partners. A company has been organized with a capital of $500,000 and operations are being resumed with a modern plant, including a 10-drill compressor and a 10-stamp mill.

Everything is being put in readiness for extensive shipment of iron ore from the Moose Mountain mines, north of Sudbury, from Key harbor on the Georgian bay to the lower lake ports. The mines were visited recently by a party of American financial magnates interested in the iron and steel industry, including John W. Gates and J. F. Harris, of New York; P. W. Ogilvy and Leonard Miller, of Chicago; John Lambert of the American Steel & Wire Co.; C. B. McCullough, of the Lackawanna Iron & Steel Co., and Joseph Sellwood, of Duluth. The interests represented were mainly those of steel companies independent of the U. S. Steel Corporation, and it is expected that Moose Mtn. may become an important source of supply to American blast-furnaces. The project to establish a blast-furnace and allied industries on a large scale at Toronto, which was in contemplation before the period of financial stringency set in, is not likely to be resumed under present conditions.

JOHANNESBURG, TRANSVAAL.

Resignation of C. J. Price. — White Labor Problem. — Stope-Drill Contest.

Universial regret is felt in mining circles at the resignation of C. J. Price, the general manager of Eckstein's Central Administration. Mr. Price came to this country from the Black Hills, South Dakota, about twelve years ago, and has established a record of which any mining man may be proud. His first important post was that of manager of the Geldenhuis Deep. On that mine the success of the deep-level mines of the Rand very largely depended, for it was the first one to start. When Mr. Price went to this mine it was losing money. When he left it, a few years later, the mine was making about £20,000 profit per month. After serving on the Crown Deep, Mr. Price was given the important position of general manager of the Central Administration, and much of the splendid showing in the reduction of working costs at this group is due to his energy and capacity. It is with extreme regret that his many friends on the Rand learn of Mr. Price's return to America. He is one of the 'old guard,' one of the engineers that have helped in the making of the Rand, and it is always regretful for a mining community to lose such men. Mr. Price's place will be taken by W. W. Mien of California.

Quite an agitation is in progress over the white labor question. A few weeks ago, the majority report of the Government Commission was handed in, and now the leading spirit of that commission, F. H. P. Creswell, is stumping the Rand and urging the people to insist on legislation along the lines recommended in the report. From a purely political point of view, there is great weight in what Creswell and his friends preach. They show that the tendency is for the total wages paid to white men to decrease, while the money given to Kaffirs in wages keeps climbing up. The Transvaal shows no signs of expanding, and unless the white youths now growing up in our midst can be absorbed by the mining industry, there is little chance of their finding employment. The cause of white labor in the Transvaal is one for which Mr. Cresswell has suffered much. While few engineers agree with him in these conclusions, no one can help admiring the persistency and courage he shows in this single-handed contest. The wealth and intelligence of the Rand are against him, but he keeps pegging away, and his arguments are beginning to sink into the hearts of the white workers, especially of those few who expect to live in the Transvaal all their lives, and bring up families here. The wisest policy for the mines to follow now is to take on white men wherever possible, even if they are a bit more expensive for the present than Kaffirs. They must show a desire to solve the problem of the unemployed white or the Government is liable to pass laws compelling them to do more for the white inhabitants of the Transvaal. The departure of the Chinese has not helped the unemployed white one bit. There are ample Kaffirs for all requirements. The partial failure of the Gordon drill has been a great disappointment to those who hoped to find a solution of the unemployed-white problem in the use of this machine in stopes. The latest reports from the mines experimenting with the Gordon drill are far from encouraging. This machine made a great stir, and won the prize in the competition, but like a good many other things in mining, it takes time to develop it to high efficiency in practice. But the search for a suitable one-man stope-drill has not ceased. The Government and the Chamber of Mines are offering large prizes for a suitable drill. A stringent contest will start next year, and as ample time is given, it is thought that makers from all parts of the world will take part. Fame and fortune awaits the man who can successfully solve the stoping problem of the Rand, by the use of a one-man machine in the narrow stopes, whereby a white man will be able to break rock as economically and as satisfactorily as the Kaffir now does by hand labor. The first prize of £4000 will be awarded to that entry for which the total cost divided by total footage drilled by all machines of that entry during the competition is least.

GUANAJUATO, MEXICO.

Effect of Mining Law Revision.—Floods and the Drainage Tunnel.—Mexican Central Branch to the City.—Mine Developments and Output.—Magistral Smelter, Zacatecas.

The effect of the anti-foreign articles in the proposed new mining law is already being felt in several parts of the Republic, for it is known that a number of representatives of foreign capital have been wired by their principals to hold negotiations in abeyance pending action upon said articles; and it is believed that several large deals that were about to be closed will fall through, or at least be long delayed, in consequence. Many influential Mexicans are working against the articles in question, and even the Minister of Fomento, Olegario Molina, originator of the measure, has found the opposition so great as to wish to shift the responsibility from himself and his

Guanajuato After the Flood, 1905.

department and have the bill presented to Congress, so that the elected representatives may be held liable for the results. As that body has adjourned, the new measure will have to be passed upon by the President, or held until the next session of Congress in September. The latter expedient will mean that improvements and developments by foreign corporations will be held in check until then. The probabilities, therefore, are that the President will take action, and the belief is that the articles will be so altered as to simply require foreign companies to register in accordance with the Mexican law, and to have a legal representative resident in the Republic.

Another deluge visited Guanajuato on June 4 and threatened great devastation. While it lasted the fall of water was about twice as heavy as during the flood of 1905, though of much shorter duration. The great Porfirio Diaz tunnel, which was driven for drainage purposes, has demonstrated its usefulness. It is claimed that this alone saved the city from great loss of life and property. Considerable damage was done, particularly to the property of the Guanajuato Light & Power Co. At the conclusion of the tunnel-connections the covering over of the river through Guanajuato will be continued, as it is but an open sewer and an eyesore to the place. Though the Guanajuato Reduction & Mines Co. is treating 500 tons per day in its cyanide plant with great success, and the percentage of extraction has been materially increased since the installation of the Butters filter, it is doubtful whether the additions contemplated will be made during the continued low price of silver. Through train service in and out of Guanajuato was quietly inaugurated by the Mexican Central railway, on June 10, and this old camp is no longer at the mercy of the mule-car. The Mineral Belt railroad hopes to have its road completed by January 1, 1909, and new machinery will be ready to go in at that time. Development work is not waiting upon that, however. The San Cayetano, so long idle, is being opened up and developed; the Ruby tunnel, driven by E. J. Kimball, is in ore and shipping; the San Diego, on the Refugio vein, is showing ore rich in ruby silver; the Tres Coronas is in ore, and the owners are preparing to put in a small mill; the Guanajuato Amalgamated Gold Mines Co. is sending excellent ore from its Jesus Maria mine to its 100-stamps and a cyanide plant; the long tunnel of the El Roble (of Corwin & Greene) has cut the vein at a depth of 1000 ft., where good ore has been found; Pinguico keeps up its record for phenomenal richness; and the Humboldt, adjoining the Pinguico, is sinking a 1000-ft. shaft.

The Magistral smelter at Zacatecas will have a capacity of 300 tons per diem. The company has no intention of entering into competition as a custom smelter, and no statement to that effect was ever officially given out. Our previous reference to this was based upon a current rumor, which was generally accepted as a fact. The deal for the Bote has been called off by the present owners. The Mala Noche, which is owned by the Guggenheims, is not being unwatered.

BISBEE, ARIZONA.

New System of Ventilating.—Comparison of Fan and Compressed-Air Injector Efficiencies.

In the Copper Queen mines, the small ½-hp. electrically-driven ventilating blowers have recently been replaced by a new type of compressed-air blower, which is proving satisfactory. The principle upon which this new blower works is the same as that of an injector. A jet of compressed air passes first through a small nozzle, and then through three succeeding nozzles, each larger than the preceding one. This compressed air draws in free air around the sides of the nozzles and the whole is discharged through an air-pipe into the face of a drift or the top of a raise. The compressed air is delivered to the blower through a ½-in. pipe. The first nozzle, which is made of brass with a steel casing inside to prevent injury, has an opening $^{1}/_{16}$ in. diam. The comparison, as worked out with a fair degree of accuracy in the Queen, between the electric blower and the compressed-air blower, is as follows: Discharging through 300 ft. of 6-in. pipe at the elevation of Bisbee (5300 ft.), a 330-watt electric blower delivers 300 cu. ft. of air per minute. This is known as a ½-hp. blower. The 5-in. compressed-air blower with 95 lb. air-pressure, and a $^{1}/_{16}$-in. nozzle takes 19 cu. ft. of free air per minute, and delivers under the same conditions 380 cu. ft. of air per minute. The cost of steam to compress the air for the air-blower is about four times as great as to generate the power for the electric blower, or running them both continuously, the cost of power for the air-blower is about $6 per month more than for the electric. To offset this increased expense for power, about $6 per month is required for inspection, oils, and repairs on the electric blower, while these items amount to almost nothing on the new blower. The initial cost of the electric is more than three times as great as that of the air-blower. As a rule, the compressed-air pipes are in the drifts, carrying air for the machine drills, while often electric wiring has to be done especially for the electric blower. This would be more often true in the future, as the amount of under-

ground electric lighting is being decreased. Often a small station has to be cut for the electric blower, while the other type can be put up wherever there is room for a 6-in. air-pipe. Another advantage is that increasing the length of the air-pipe, the amount of air delivered by the air-blower does not decrease as rapidly as with the electric, on account of less friction in the blower itself. This new blower is equipped so that it can be used for exhausting the bad air from the drifts instead of blowing in fresh air, and the efficiency ought to be nearly as great. For anything larger than a ½-hp. blower, the cost of compressing the air is prohibitive; the large electric blowers being only slightly more expensive to maintain than the smaller ones.

BUTTE, MONTANA.

North Butte Co.—Butte Coalition.—Damages by Floods.—United Copper Co.—North Butte Extension.

The North Butte Mining Co. will open the Edith May vein on the 2000 and 2200-ft. levels in about three months. The stations and skip-pockets at those levels will be completed in about 40 days, when cross-cutting will be started. The North Butte is mining on the 800, 1000, 1200, 1600, and 1800-ft. levels and is hoisting about 45,000 tons of ore per month, half of the ore being first class, which averages about 8% copper; the rest is second class and the average of all the ore shipped is running form 5½ to 6% copper. The North Butte has an amount of ore blocked out sufficient to last the company for years. The cross-cuts on the 1600, 1200, and 1000-ft. levels will be extended to the Berlin group of claims. Serious litigation is threatened against the La France Copper Co. by the municipality of Walkerville. The company is operating a dry process metal separator at the Lexington mine and is creating so much dust that the little city north of Butte is suffocating. An analysis of the dust in the drinking water discloses 2% copper, 19% zinc, 9% iron, 45% sulphur, and 4% silica. The council of Walkerville has directed its attorney to institute an injunction suit against the La France Company.

The Butte Coalition Co. is developing in the Tramway and Minnie Healey mines. Until that is completed actual mining will be confined to the Rarus, from which about 850 tons of ore are shipped daily. Between 10 and 15% of it is first-class ore, averaging better than 10% copper. The entire output of the mine averages 5½%. A large 'chippy' engine—20 by 72 in.—is used at the Tramway for sinking and development work, but a magnificent hoisting engine has also been installed, though it will not be used much until operations on a large scale are started. The engine is a duplicate of that at the North Butte mines—32 by 72 in.—and capable of working to a depth of 3500 ft. It is expected to add about 30,000 tons per month to the output when the Tramway begins producing. The Tramway claim itself is practically undeveloped.

The annual report of the Butte Coalition Mining Co., including a statement of details by A. C. Carson, the general manager, as to operations during the year ending December 31, 1907, contains some facts that were new even to Butte. Mr. Carson reports that the Anaconda Co., working through the Diamond shaft, has exposed some fine orebodies within the boundaries of the Parnell claim, at a depth of 1200 and 1500 ft., and that development work is now being done to determine if the orebodies belong to the Parnell or to some adjoining claims, owned by the Anaconda Co. The Butte Coalition Co. owns a fourth interest in the Parnell, and if it should develop that the Parnell is entitled to the veins, the Coalition Co. would gain considerable addition to its reserves. The financial report shows that the cash on hand at the end of the year was $3,503,156 against $4,169,082 the previous year. Most of the decrease is accounted for by development work, but it is understood that the company also paid a large sum to the Anaconda Co. as rebates on copper.

Floods and consequent damage to railroads and smelters during the past two weeks in Montana greatly impeded mining, and the June production of copper will be reduced fully one-third, as compared with the production in May. The mines of the Boston & Montana Co., which produced nearly 3500 tons of ore per day, have been closed for two weeks, and some will probably remain closed for a month or six weeks longer on account of washouts on the Great Northern railroad between Butte and Great Falls and because of damage by floods to the smelter itself. A portion of the power-house of the smelter at Great Falls was wrecked by the flood and the water from the head-race ran through the power-house aud over the machinery. The lower works of the smelting plant were flooded, and the north wall of the head-race was broken out by the flood. A portion of the wall of the head-race was dynamited to divert the flood, but by the time that had been accomplished most of the damage had been done. The Butte, Anaconda & Pacific railroad, between Butte and the Washoe smelter at Anaconda, was badly damaged by washouts and by wrecked bridges, resulting in a suspension of traffic for four or five days, and a consequent closing of all the mines that shipped to Anaconda, including those of the Anaconda, North Butte, Butte Coalition, Butte & Boston, Washoe, Trenton, and Parrot companies. The Clark mines and smelter were also shut down for several days on account of water that overflowed the smelting plant, and the storm that put the electric car line out of business in Butte, stopping ore transportation from the Original mines.

The 'report' made to stockholders of the United Copper Co. at the recent New York meeting caused little surprise or comment in Butte, where little is looked for and less expected from the company. The public has always been kept in the dark as to United Copper holdings and income, but in Butte it has been known that many of the so-called assets of the company were of no value and were practically fictitious, as they included the former Heinze companies now owned by the Butte Coalition Co. The treasurer's report shows that for the fiscal year ending June 1, 1908, the income was $861,023 as compared with $6,565,592 the year before. The surplus 'available for dividends', was $800,482 as against $6,475,007 for the previous year. The Heinze directors were elected, the board being composed of F. A. Heinze, John MacGinnis, Stanley Gifford, Chester Glass, H. G. Abel, Sanford Robinson, William J. Curtis, A. B. Cook, and Carlos Warfield. Mr. Heinze declined to furnish the stockholders with any detailed information, saying such statements were not usual. He said the debts of the company, or its subsidiary companies, were not pressing, and the $1,100,000 would pay off the floating debts. The Ohio Copper Co., one of the subsidiaries, has an indebtedness of $500,000, and the Stewart Mining Co. about $60,000. The company has no producing mines, but Mr. Heinze says the Ohio, Stewart, and La France could be made producing, but there is no use to do so at present prices of copper. The United Copper Co.'s receipts come from securities, but the company owns few dividend paying stocks at present.

The North Butte Extension Copper Mining Co. seems to have become involved financially very late in the history of the panic. During the past week several attachments have been put on the property, one for $5000, due on a note given by the company to L. A. Walker and John A. Ryan. Stockholders in the East appear to have had advance notice of impending trouble, for the stock was thrown on the market in large blocks, the sales in one day on the New York curb amounting to 35,300 shares, forcing the price down from $2.50 to 40c. per share. It is surmised that a lot of stock owned by promoters or insiders was released and thrown on the market. The company has not paid current wages and operations have been suspended.

The new Tramway shaft of the Butte Coalition and Butte & Boston Co. is now down 1400 ft., and from it the Minnie Healey orebodies are being opened at that depth. It is probable that it will be a long time before the upper levels of the Minnie Healey can be worked again, because of the gas from the fire that is smouldering in the old stopes and eating into the old orebodies. The fire is well confined, but the gas breaks out most unexpectedly.

Concentrates.

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Cold chisels for use on cast steel should have their entting edges meet at an angle of 65°, for use on brass an angle of 50° is better, and for copper and soft metals use 30 to 35 degrees.

Compressive strength of timber is materially reduced by the presence of moisture, be it sap or water absorbed after seasoning. Seasoned wood, having less than 12% moisture, is from 75 to 100% stronger than green timber.

The Dos Estrellas Mining Co., operating at El Oro, Mexico, has a capital of only ₱300,000, in ₱1 shares. The company has paid to date the splendid sum of ₱6,510,000, the last dividend being 50cv. per share, in April of this year. The present market price of the shares is ₱95.90.

A man can pass over 12.5 times the space horizontally that he can vertically, with the same expenditure of effort. A 165-lb. man can, by walking in alternate directions upon a platform supported on a fulcrum at its centre, produce work of 3,984,000 foot-pounds per 10-hr. day.

Files clogged with copper or brass should be cleaned with nitric acid. For iron filings use first blue vitriol, and after washing it all off with water, dip the file in nitric acid. Be sure to wash all the acid off, and rinse in water containing caustic soda. Then thoroughly dry the files.

The modern steam engine utilizes as effective work 12.7 to 15.7% of the units of heat introduced as fuel under the boiler, while the gas engine shows an efficiency of 19 to 23.2% of the heat units in the fuel used. This mere thermal superiority of the gas engine does not prove, however, that it has the greater commercial economy in all cases.

Astronomical time, or local mean solar time, is the time that would be kept by the mean sun, and is obtained from Standard, or railroad time, by adding or subtracting 4 minutes for each degree of longitude that the place of observation is east or west of the Standard meridian. The astronomical day begins at noon of the civil day of the same date, and is reckoned from 0 to 24 hours.

Tight shot is a term used by coal miners for a charge which is too deeply laid, or as they say, 'too much on the solid.' The result is that instead of doing the desired work, the gases escape through a blow-out, at a high temperature, and are more likely to produce explosions of coal dust or fire-damp than when the shot expends its heat in doing the work intended in blasting.

Rupture-load for a 'cap' or other mine-timber may be calculated by the formula $W = 2\ \frac{1.28\,bd^2}{L}$ where b, d, and L represent breadth, depth, and length between supports, in inches, S the mean tensile and crushing strengths of material at $^2/_3$ its experimentally determined value, and W the ultimate strength. The formula assumes the cap or beam to be uniformly loaded throughout its length.

Chrome iron-ore has long been used as a lining for reverberatory furnaces in copper smelting. It resists corrosion better than any other substance yet discovered. It is useful for the bottoms, bridges, and sides of the furnace, and for the partitions and floors of the flues, especially when the ores contain some lead. The chromite should be used in the form of large blocks, fitted together as accurately as possible, the interspaces chinked with smaller pieces, and the joints filled with a mixture of crushed chromite and zinc-blende, which is very refractory. Such a lining will last many times as long as the best fire-bricks. For the firebox-lining bauxite bricks are superior to any other kind.

Crushing-rolls may be kept true by placing a block of emery so that it will rest by gravity upon the rolls while they are in motion. This hint was given in 'Concentrates' about a year ago. A correspondent writes that he has applied this suggestion with great success. He says, "I got some carborundum blocks and fitted them onto the frame of a set of 30 by 16 in. rolls so that they pressed by their own weight on the back of each roll. The frame for the blocks was made and fitted by the blacksmith. The carborundum blocks were 8 by 3 by 3 in., and cost delivered (in Queensland) $2 each. They lasted 2½ months, and kept the rolls perfectly true, without taking off much metal. The blocks can be renewed in a few minutes. The saving in time from not having to turn up worn roll-shells, has resulted in an important saving in money. This simple arrangement ought to be more widely known."

Pitot's tube is a device for measuring velocities of streams by means of the velocity-heads which they produce. In its simplest form it consists of a tube open at both ends, bent in the shape of the letter L. When held in a moving body of water, so that one leg is horizontal, with its open end directly facing the current, the velocity is measured by the vertical height to which the water rises in the other leg. This height, h, is theoretically equal to $v^2/2g$. Therefore the velocity, v, is approximately equal to $\sqrt{2gh}$. As constructed for actual use, Pitot's apparatus consists of two tubes, one of which faces up-stream and the other at right angles to it. Both of these tubes are connected to a different gauge, by means of which the difference of head may be measured. It has been found by experiment that the actual velocity is always less than $\sqrt{2gh}$, and that a coefficient may be deduced for each instrument by moving the apparatus in still water at known rates of speed. Such a coefficient will probably have an average value of about 0.9. The pitot tube has the advantage that no time-observation is required to determine velocity, and it has been proved to be an instrument of considerable precision, especially in the measurement of high velocities.

Discussion.

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy.

Waters, Meteoric and Magmatic.

To the Readers:

Gentlemen:—The article under the above title contributed by Mr. James F. Kemp in our issue of May 23 will have proved both interesting and suggestive to mining geologists. The Professor of Geology in Columbia University makes even meteoric waters sparkle with a touch of humor and into those emanating from the magma he injects some of his own cheerful spirit, so that a subject which could not well be dry is made as attractive as viticulture.

As to the magmatic waters, I leave them to the physicist; they are much beyond my ken; there is nothing I can contribute to the elucidation of what is essentially a deep subject, but in regard to meteoric waters, their distribution and character, I can venture—as once a mining engineer—to make some observations. Mr. Kemp refers to the theory of a water-zone suggested by me in the discussion on ore deposits that took place before the Geological Society of Washington in January 1903. Two years earlier he had himself contributed a paper on a kindred subject to the *Transactions* of the American Institute of Mining Engineers (Vol. XXXI, p. 187), and in that paper he had incidentally referred to the absence of free water in the deeper workings of mines, stating that it was such as to disprove "the conception of universal ground-water." But I went much further and cited evidence to indicate the existence of a water-zone, the top of which was the 'water-level' of the miner, while the bottom of it was usually only a few hundred feet deep, as indicated by a horizon beneath which mines become dry if care be taken to prevent the water following in the wake of excavating operations, that is, if the water is 'caught up' and pumped to the surface. This idea was discussed by me in a paper entitled 'Water in Veins—A Theory,' published in *The Engineering & Mining Journal* of March 14, 1903. It elicited some valuable discussion by W. H. Weed, G. Chalmers, J. E. Spurr, W. A. Prichard, Bernard MacDonald, and others. And then the subject was dropped. The idea did not seem to commend itself to geologists as of any particular importance, although to me, with all the egotism of a father, this child of my imagination seemed fitted to be of service in mining geology.

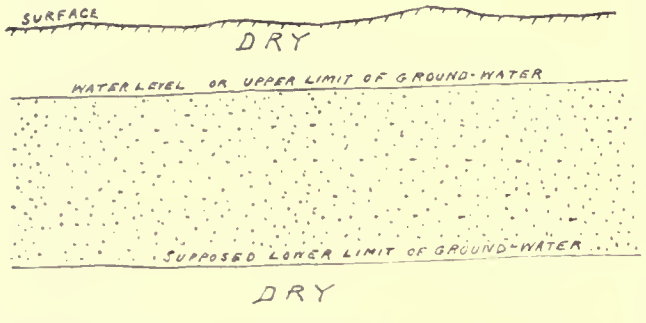
It does seem as if our understanding of ore deposition cannot be placed on a sound basis until we have obtained a clear notion of the distribution of the ground-water, that is, water of meteoric origin which accumulates a short distance below the surface and into which our mine workings penetrate. Most of the metalliferous ore extracted from mines comes from the comparatively shallow zone within which the ground-water is so important a factor, both to the miner and to the geologist. Acknowledged authorities such as C. R. Van Hise speak[1] of "the belt of saturation" below the top level of the ground-water as being "limited to a depth of 10,000 metres," and the idea has long prevailed among most writers on ore deposits that while there is a well-defined upper limit to this ground-water (as Posepny emphasized by his introduction of the term 'vadose'), the lower limit is vague, ending at the region of rock-flowage, at all events, at a horizon so far below the deepest possible mine workings as to be a matter of surmise. The ore deposits known to man have been formed well within the 10,000 metres or 33,000 ft. of the supposititious water-saturated belt of the earth and yet geologists have assumed the formation of fissures and other openings through which mineral solutions have coursed so as to precipitate their burden of metallic elements. This is the conception running all through the text-books on geology and the essays on ore deposition. We might as well imagine a mountain stream entering a morass, passing through the morass, and issuing at the other end without loss of its individuality; moreover, the accepted conception of vein-formation within "the belt of saturation" supposes the stream to enter the morass without losing its identity, flowing through it to the farther end, with slight exchange of ingredients, and with its distinctive character unimpaired. Indeed, the water-zone has many points of similarity to a morass, for it is a region wherein both reducing and oxidizing conditions variously exist, owing to the presence of organic matter on the one hand and of entrained oxygen on the other. In the water-zone the conditions favor oxidation near its top level, and reduction near its base; while approach to the surface means nearness to the oxygen of the air, it also entails contact with organic compounds.

Observations in mines go to show that there is a shallow layer of water beneath which the rocks become rapidly less moist, and while I am aware that even the 'dry' rock of mines contains from 3 to 5% water, able to move by capillary attraction, yet there is a sudden change below the water-zone from a continuous body of water, filling every pore and every cavity, to a condition so different as necessarily to become a decisive factor in ore deposition. For instance, in the Rocky Mountain region it is the usual experience, when sinking a shaft, to strike water at a couple of hundred feet below the surface, then the inflow of water increases until the shaft has been sunk to six or seven hundred feet, where the maximum inflow is encountered and the largest pump-equipment is installed. On resumption of sinking, if the water overhead is caught and pumped to the surface, the influx of further water decreases, and at a thousand feet or thereabouts the ground is 'dry,' that is, there is no free water visible, although on analysis it will be found that the dusty rock contains at least 3% moisture. However, there is a marked tendency for moisture to diminish and for free water to cease. To the miner the fact of maximum water at a certain level is known: it is a fact indicating that he has penetrated below a reservoir or accumulated store of water. In mining operations, the shaft is apt to continue to be wet long

[1] 'Genesis of Ore Deposits.' Page 291.

after it has been sunk below the level of maximum inflow because the lateral openings on the vein, with the connecting stopes and raises, afford a chance for the water from the upper portion of the mine to seep downward. At the risk of destructive criticism I shall express these ideas by means of diagrams; thus in Fig. 1 there is illustrated the first recognition of a water-zone; in Fig. 2 a shaft is sunk and the workings from below the under limit of the water-zone tap the water overhead so that a V-shaped depression is formed in the bottom of the water-zone. But this is what happens when fault-fissures and other openings exist; moreover, the rock under the water-zone is of varying texture, it is fractured in many directions, it is traversed by systems of fissures, and into these the ground-water descends to a varying extent, so that the net result is to make the lower limit of the water-zone not a plane (or a line in cross-section), but an acutely serrated and most irregular boundary, as in Fig. 3. Thus a shaft may be sunk away from a vein and yet on connecting it with a cross-cut, the water from the vein makes the shaft wet; or, again, the mine workings may have penetrated below the water-zone at one place and yet intersect it at another place, where, for instance, a fault or a cross-course

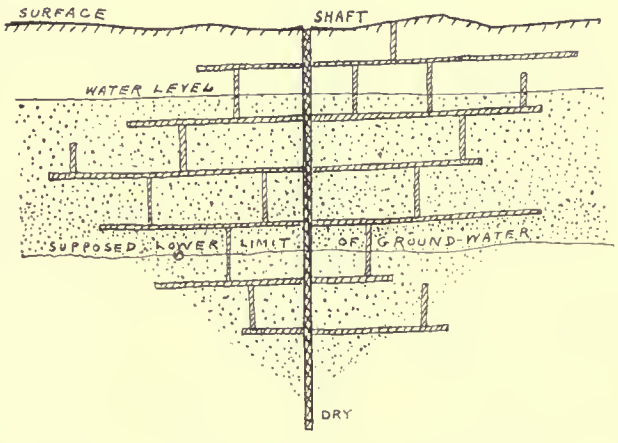
FIG. 1



has afforded a chance for the water to descend, that is, to let down the water-zone.

There is no warrant for the assumption of a water-saturated belt of indefinite thickness. If it existed, mines would become wetter the deeper they were excavated. The ability to drain whole mining districts proves that the water forms a shallow reservoir. Thus at Cripple Creek the first adits drained the upper workings of all the mines within a connected area. As the deeper cross-cuts and drifts tapped an increasing portion of the water-zone, the inflow increased and the deepest shafts were the wettest. Even when the shafts were sunk below the level of maximum inflow, the communication (through stopes and raises) with the upper workings tended to maintain a big influx and the cross-cuts that were extended in every direction in the search for ore tapped water-ways the contents of which also found their way to the deepest shafts, which thus became a 'sump' or well for the whole district. The Portland, Moose, Elkton, Mary McKinney, Moon Anchor, and C. O. D. mines, for example, seemed to be on a connected water-chanel, for cessation of pumping at any one of them increased the amount of water to be pumped by the others. Originally the upper level of ground-water was struck at 9500 ft. altitude, in seven or eight years it was lowered to 9050 ft., that is, 450 ft. of the water-zone had been removed by adits and pumps; the water-level then stood at 9050 ft. above the sea or 700 to 750 ft. below the surface of the ground

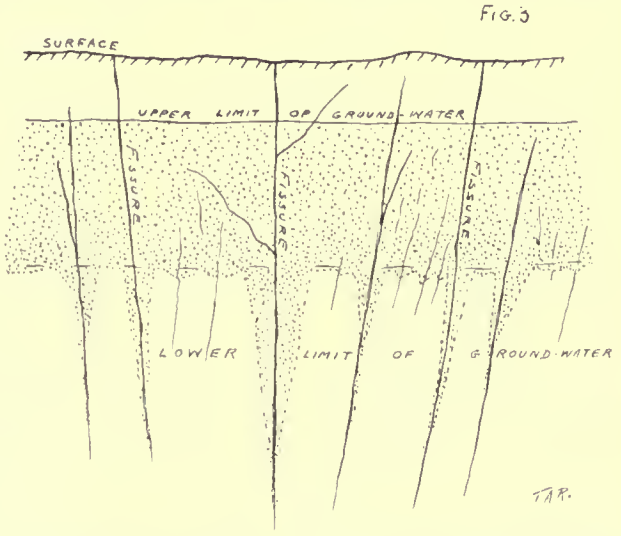
FIG. 2.



at Cripple Creek. Apparently the deep shafts were below the water-zone, for while it had required the pumping of 107,000,000 gal. to lower the general level one foot, it now needed the pumping of only 44,000,000 to achieve the same result. In the Independence mine water was struck at 370 ft. and the maximum flow (900 gal. per min.) was noted at 570 ft. Below that point the mine became less wet and in 1903 when it was 1400 ft. deep, the shaft was 'making' only 100 gal. per min. despite the fact that down to 900 ft. this shaft was connected with 16 miles of workings.

In the Rocky Mountain region generally it is usual to sink shafts after the first frost, because seepage from the surface then ceases; the wet season in the mines is during the early summer, when the frost is out of the ground and the water from melting snow penetrates through the upper workings into the deeper levels. Bernard MacDonald, formerly manager of the Le Roi mine, states that at Rossland,

FIG. 3



in British Columbia, during the spring (from March to July) "the water in the mines increases about 30% *over* the annual average" and in the dry season (August to October) the flow "decreases to about

25% *under* the annual average." This emphasizes the superficial origin of the water in mines. Moreover, in the desert regions of Arizona, Africa, and Australia the mine workings at a depth of 800 or 1000 ft. are actually *dusty*. In Western Australia the ground-water level was encountered at 40 to 50 ft. in many shallow prospects that I examined, but in the large veins of Kalgoorlie water was struck at from 75 to 100 ft., the maximum inflow was at about 600 ft., and at 900 to 1000 ft. there was no water. Even at a greater depth there would be (according to W. A. Prichard) sudden inflows due to boring into a watercourse, but such flows were brief and stopped suddenly, indicating their restricted character. They were the elongated V-shaped depressions of the water-zone such as are shown in Fig. 3. At Rossland, according to Bernard MacDonald, water is encountered at 25 to 50 ft. and the inflow increases up to a depth of 200 to 350 ft. Below 350 ft. the decrease is at first gradual, then with added depth it becomes rapid until at 900 ft. there is only a slight seepage, and below 1000 ft. the workings are dry.

In most mining districts the shafts sunk at a later date find the water-level farther down. Only the first shafts strike the water at its original level; for each successive drainage adit depresses the water-level and each mine that goes below the water-zone acts as a sump to collect water from the adjoining area. In the Morro Velho mine, in Brazil, the new shaft sunk alongside the old cave workings was absolutely dry, care having been taken to remove the water (coming down through the old excavations) by means of a bore-hole. At Monte Cristo, in Washington, the top limit of ground-water (according to J. E. Spurr) coincides with the surface, that is, the water-zone is immediately under the surface, for it is a region of abundant rain and the ground is full of joints. Mr. Spurr estimates "the depth of the surface zone of maximum water circulation" at less than 250 ft. In the Lake Superior copper district, there is "practically no water below 1200 ft.," as I was informed by Mr. W. A. Parnall, of the Tamarack mine. In sinking the Tamarack shafts, two of which are 5000 ft. deep, it was necessary to send down water for drilling. The maximum inflow of water is between 600 and 900 ft., usually at 700 ft. from the surface. When No. 5 shaft (vertical) of the Tamarack cut the Calumet conglomerate lode (dipping at 38°) at a depth of 4250 ft., the lode was found "very dry." The surface water follows the workings of the Calumet & Hecla down to the deep levels, but a new drift in virgin ground soon gets into dry rock. In the Atlantic mine three-fifths of the water is "taken up" at the seventh level, that is, 450 ft. below the surface. Many of the mines were started in swamps and these serve to collect water each spring. The water of the Lake Superior mines is rich in chlorides of lime, soda, and magnesia. These salts are probably derived from concentrations in the sandstones overlying the copper-bearing series to the west, that is, on the hanging-wall side. It is supposed that descending waters dissolve the more soluble calcium chloride first, and then the less soluble sodium chloride. They are carried by gravitative stress to the deeper horizon of the underlying trap series in which the copper is found. Even the wells near Houghton show the presence of chlorides and bromides.

In a district like Butte, where three or four successive periods of movement have caused intense and repeated fracturing, the water-zone has been depressed and the mines are wet down to 2000 ft. or even deeper. Furthermore, where, in a mineralized region, there has been faulting on a big scale, so that whole blocks of ground have been lowered, the result would be to depress the water-logged area and to permit of meteoric waters reaching an unusual depth. Emmons, writing eight years ago, ascribed the unusual secondary enrichment of the Butte veins to a rise in the water-level (and a depression of the former oxidized zone) of from 1000 to 2000 ft.,[2] this change of level being due to a regional fault.

To the miner, whose operations are limited, the belt of ground-water will appear as a zone of relatively large depth; to the geologist, who views the matter on a bigger scale, the zone will appear as a thin blanket, the top of which is approximately smooth while the bottom is very ragged. Under the water-zone is an indefinite region of dry rock and somewhere below it at an unknown depth is the source of the magmatic waters. These do not rise from gravitative stress nor are they a continuous portion of the ground-water, there is a hiatus between them and the reservoir of meteoric water; so that the old conception of rainfall descending into the earth at one place and circulating downward until by heat and pressure an upward movement was induced, is now no longer tenable, save in a restricted sense. We have a blanket of cold meteoric water, then a region of dry rock, penetrated by fractures, which become tight not far below the deepest mine workings, then still deeper upwelling hot mineralized waters of magmatic origin. As these ascend through fractures caused by movements resulting from volcanic action, or by dislocations due to readjustments of the earth's crust, they penetrate finally, near the surface, into a layer, zone, or belt of cold water, which has come from the surface and is charged with oxygen.

Having regard to the facts disclosed in mines, it seems to me that the theoretic curves illustrating the flow of underground water are fanciful and misleading. The idea that gravity is the only force to account for the circulation of the waters producing ore deposits is untenable, for there is a separation between the meteoric waters and the magmatic waters. The meteoric waters descend from the surface and accumulate at the water-zone, to be returned to the surface in places in the form of springs and artesian flows. The magmatic waters are presumed to originate at a great depth, whence they ascend with a loss of identity due to diffusion and chemical interchange during their passage through the water-zone. There has been a lot of lovely theorizing in disregard of the facts disclosed in mines and until these facts are properly accounted

[2] 'Genesis of Ore Deposits.' Page 445.

for our explanations of ore formation are bound to be incorrect.

The records of mining prove that ore deposits are non-persistent in depth, though sufficiently continuous to serve as marvelous treasuries of metallic wealth. While the deepest mines are not all non-productive, there is no known ore deposit of which it cannot be said confidently that the mechanical ingenuity of man is likely to be able to enable him to go deeper than the ore will persist. Having regard to the size of the earth, having regard even to the relatively thin section of it represented by its geologically known exterior, this depth of ore deposition and mining is insignificant. All the evidence is in favor of the essentially superficial character of ore formation; in other words, the precipitation of ore, and especially the concentration that makes the richer bodies of it, is measurable from the surface accessible today and has been affected by geological conditions near that surface. Of these conditions the most important is the existence of a blanket of meteoric water charged with oxygen and salts leached from the oxidized zone overhead.

This is not the time, nor is there space, for me to refer to the changes in the mineral composition of veins from the surface downward, but I venture to say that if the successive changes in the component minerals of ore deposits were investigated, there would be plenty of evidence to link the water-zone with the variations observed at different horizons. Whether my explanation be correct or not, it is quite certain that significant facts observed in mining have been overlooked by many leading authorities, such as Posepny, Van Hise, and others who have written lengthily and wisely on the subject of ore deposits. Until the known facts concerning the distribution of water underground, within the region penetrated by the miner, are explained so as to harmonize current theories with these facts, and not the facts with the theories, we shall make no sure progress in the elucidation of the problem. In any event, it is safe to say that no mining engineer investigating a particular district and endeavoring to ascertain the probabilities of persistence of ore in that district, can arrive at any safe conclusion until he has ascertained the position of the water-zone, its extent, and the part it has played in favoring those secondary enrichments upon which man depends mostly for his store of metal.

T. A. RICKARD.

San Francisco, June 10.

The Rights of the Miner.

The Editor:

Sir—Having been a prospector myself, I speak from first hand in disagreeing with Mr. Van Wagenen in some of the points raised in his recent article on 'The Rights of the Miner', appearing in your magazine. There is much to be said on both sides of the question of extra-lateral rights, but I take it to be a question which chiefly concerns the mine-owner and not the prospector. The apex law has led to endless litigation in the United States, and made such a mess of things in Canada that everyone was heartily tired of it and glad to see it repealed. As far as I know, the large majority of Canadian mine-owners are perfectly satisfied with the present law of vertical boundary planes. If the prospector makes a good find he can sell it, irrespective of any limit the law may set as to following the ore in depth. If he wishes to protect himself he can stake an extra claim in the direction of the dip of his orebody, though one would think a width of 1500 ft. would be ample. That the square boundary law does not deter prospectors from exploring the mountains of Canada is shown by the fact that there are hundreds of them in British Columbia alone. I do not understand how Mr. Van Wagenen could make such a statement as: "There is not a prospector in the whole of the British Northwest." As a matter of fact, there is a big rush on at this time for the Skeena River country, and it is not only the placer gravels on Findlay river that are attracting the adventurers, but as the new line of the Grand Trunk Pacific through Yellowhead Pass to Prince Rupert will open up a large mineral belt, prospectors are busy all the way from the head of the Columbia to the Peace river, looking for silver, lead, and copper, and several very encouraging finds have been reported. There are numbers of prospectors in even such an old established community as this. At the first signs of warm weather last month fully half our mine crew deserted us and went into the hills prospecting. The Canadians should do away with the Miner's License Act and lessen the burdensome taxation on ore shipments. In the United States something could be done to aid and protect the legitimate prospector by putting a crimp in the activities of the 'pegger'. The latter is an abomination. He is a man of no knowledge of mines or minerals; as a rule an ex-barber, shop-clerk, or bar-keeper who follows on the heels of the prospector and, smelling a 'strike' from afar, rushes in and stakes the rest of the county. In Nevada no attention is paid to the law requiring that mineral be found in place in order to originate a valid location, and the liberal Nevada law allowing the locator to remove the equivalent of the usual 10-ft. hole, that is, 240 ft., any way he chooses to dig it, has led to absurdities. At Bullfrog I saw four claims staked out on the flat sands of the Amargosa desert, each decorated with what had the appearance of a croquet court, the pegger's 'location hole' 12 by 20 by 1 ft. deep. In California matters were even worse. It having been reported that the famous 'Shorty' Harris had struck it rich in the Panamint range, a great crowd poured out of Rhyolite, crossed Death Valley, and staked the whole of the Rosebud district within a week. As the California law (or rather, lack of it) required no location work whatever, men staked as many as 40 and 50 claims, and legitimate prospecting in the district was killed for the remainder of the year 1905 and all of 1906.

The pegger or 'pencil prospector,' as he is sometimes called in the Southwest (his common Nevada name would not look well in print) certainly needs squelching, and the real prospector should receive every aid we can give him. J. V. RICHARDS.

New Denver, B. C., June 4.

COBALT, ONTARIO.

Written for the MINING AND SCIENTIFIC PRESS
By H. B. SMITH.

Since the first discovery of ore at Cobalt, during the construction of the Provincial railroad in 1903, many changes have been wrought in the appearances of the district. The country around Cobalt is a rocky glaciated area, dotted with numerous connected lakes. The whole region at the time of the discovery was covered with green timber, which had grown up since the lumbermen removed the virgin forest some twenty years ago. Since mining operations started upward of 1500 acres have been cleared in the vicinity of Cobalt, Glen, and Kerr lakes. The rocks of the district are covered in many places by glacial drift, but this is seldom more than a few feet thick. In the flats between the hills, swamps are frequent and must be drained before prospecting can be attempted. The energetic competition of the early prospectors is well illustrated by the accompanying cut showing multiple locations, the stakes indicating the number of locators laying claim to one mineral discovery. As many as 40 men were simultaneously prospecting this claim, which became the property of the one who made the first discovery of mineral that would pass the government inspector's examination. A claim consists of 20 acres.

The general method of prospecting is as follows: Trenches are run in various directions and the surface of the rock cleaned and prospected as the trenching progresses. The digging is usually done by Italian laborers, while an experienced prospector follows them up, cleaning and carefully examining all cracks and joints for mineral indications in the rocks uncovered. During the summer of 1906 the Nipissing Mines Co. attempted to substitute hydraulic sluicing for the slow trenching method of prospecting, and a pumping station was established on the shore of Peterson lake. A centrifugal pump furnished the water for the operations, which were directed against the slope above the lake. This method was soon abandoned, but not until after several new veins had been exposed. The New Vein in the Nipissing is shown in the accompanying cut. The two picks held by the engineer indicate the width of the vein. The sacks of ore reveal that it is sent to the smelters for treatment.

The almost vertical veins of the district range in width up to about 20 inches. The extent of these veins has not been fully determined, as few have

The Lawson Vein.

New Vein in Nipissing.

Multiple Locations.

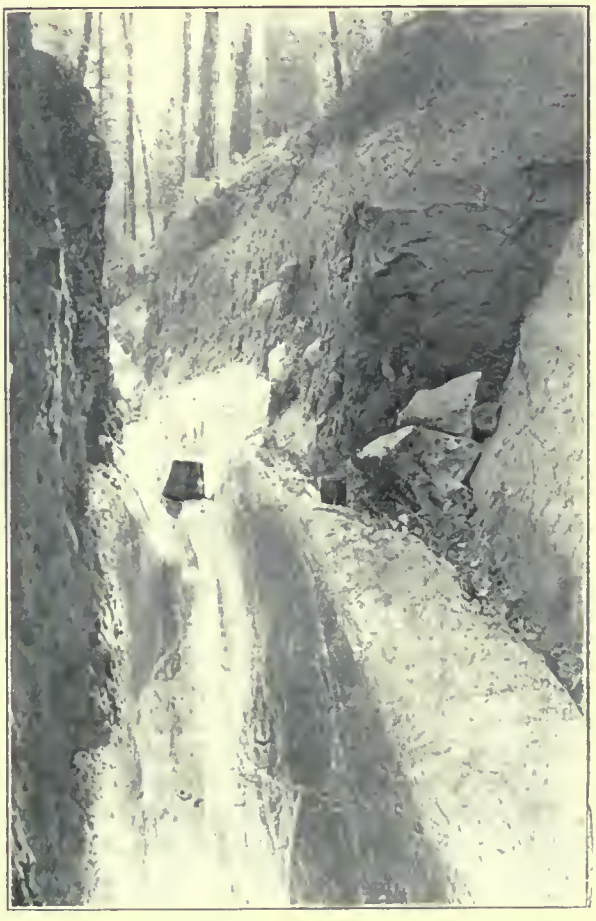
been uncovered for more than a short distance. Some branch out into veinlets and are lost, or pinch out and may be picked up farther on. In places the veins follow the warped course of the joint-planes in the country rock. The principal constituents of the ore are native silver, argentite, and argentiferous smaltite, but native bismuth and niccolite also occur in most of the deposits. In a few veins the cobalt and nickel minerals are found with little or no silver, as in one vein of the Nipissing Mines Co. on Cobalt hill. The gangue material is calcite, but it is usually found only in small quantities. Quartz gangue is rare. The absence of the sulphides of the base metals

Calcite Vein, 12 to 16 Inches Wide. The Striations and Grooves Are Due to Glaciation.

in the vein-filling is a rather singular fact. Chalcopyrite, galena, blende, and pyrrhotite occur in veinlets and flats in the country rock, but even here pyrite seems wanting. These veinlets are older than the silver-cobalt deposits.

Most of the rich silver veins of the district are in the Lower Huronian formation. A hill of Lower Huronian is shown in one of the cuts herewith. It is Lot 401 of the Nipissing property. A narrow dike of dark diabase cuts the hill at right angles to what appears to be a fault-scarp, at the foot of the man shown in the photograph. Note the anticline on the right. At the base of this formation is a banded slate on which rests an impure quartzite, in turn capped by a conglomerate member. The Lower Huronian formation rests on the older Keewatin series of greenstones, which outcrop in a few localities in the producing district and in a few instances contain rich silver veins. Vein No. 26 of the Nipissing Mines Co. is an example of a rich silver vein in the Keewatin, while the veins of the Green-Meehan Mining Co. in the township of Bucke are

Hill of Lower Huronian Conglomerate.



A Vein in Diabase or Gabbro, Showing Depth of Drift Covering.

other examples. At shaft No. 6 of the O'Brien mines, a rich silver vein in the diabase has been cut at the 100-ft. level by both east and west drifts.

The weathering of the vein matter in some instances has reached a depth of 15 to 30 ft., while at other points little or no alteration of the filling is observed. It has been suggested that very little alteration has taken place since the glacial period and in support of this view attention is directed to

the native silver outcrop on the Lawson property, where the native silver and country rock alike still show distinct glacial striations. The Lawson vein carries from two to eight inches of bright native silver, also exhibiting marks of glaciation. The removal of the overburden of drift has exposed the vein, which is seen in the bedrock. This vein has been involved in litigation.

Up to the close of 1906 the ores of the district were won by underhand stoping in open-cuts, but at the end of 1906 many shafts were put down, power and hoisting plants were installed, and at present the wasteful open-cut method of mining has been practically abandoned. More than one mine is pumping extra surface water now owing to these old workings. In the open-cuts hand-drilling was resorted to, and even now shafts are sometimes sunk by this method, but air-compressors, from 5 to 20-drill capacity, have been installed throughout the district and all underground work is done by machine-drills. A number of hoists are also run by compressed air.

The typical shaft in the district is 5 by 8 ft., inside measurement, with a hoisting compartment, fitted with a cage, and a ladder-compartment which also contains the air, steam, and water-pipes. Two-compartment shafts, as well as adits, however, are also found in the district. The ore is hoisted from the mine in cars and trammed to the 'rock-house,' where it is washed and hand-picked into three grades. The first grade will usually run over 2000 oz. per ton; the second grade, over 150 oz.; the third grade is under 100 oz. per ton. The first two grades are sacked for shipment to the smelters, while the low-grade ore is piled on the dump. Many of the miners now either have mills in operation or under construction, and several custom mills have also been built to concentrate dump-ore. The ores for the most part have been shipped to the Canadian Copper Co.'s smelter at Copper Cliff and to the American Smelting & Refining Co. at Perth Amboy, but shipments have also been made to the Balbach Smelting & Refining Co. at Newark, N. J., to the Deloro smelter in Ontario, to Denver, and to the Vivian works at Swansea, Wales.

Aside from the power-plant, shaft-houses, blacksmith shops, magazine, and office, each mining company has a bunk-house and boarding-house where the men are furnished with room and board at 60 cents per day, which amount, along with a 50-cent per month hospital fee required by the Provincial Government, is taken out of each man's check on pay-day. Both board and bunk-houses are found in various stages of perfection at the various camps in the district. At some of the mines the comfort of the men is so far considered that iron beds with springs and mattresses, in plastered, steam-heated rooms, are furnished, the building is furnished with electric lights, hot and cold baths, and ice-water is always on tap.

The town of Cobalt spreads over large area along the hillside overlooking Cobalt lake from the north. Here two large modern hotels, the 'Prospect' and the 'Cobalt,' provide for the welfare of the traveling public, while three banks furnish connections with the financial world. The rocky surface at Cobalt makes the maintenance of sanitary conditions impracticable, and in view of this fact a new town-site, called Argentite or North Cobalt, has been cleared on the edge of the clay belt two miles north of Cobalt station, and here sewage and water-works systems and a systematic arrangement of buildings is to be enjoyed. North Cobalt will be reached both by rail and by the new King's highway which connects the various mines with the railway stations at Cobalt and Hailibury.

STANDARDIZATION OF BULLION AND ASSAY VALUES.

The Committee on Bullion and Assay Values appointed by the Institution of Mining & Metallurgy (London) requests opinions and arguments upon the following points:

1. Do you approve that, wherever possible, assay values of gold and silver ores and products shall be reported in ounces and decimals, or pennyweights and decimals, rather than in ounces, pennyweights, and grains?

2. Do you approve that assay values of alluvials shall be reported in grains and decimals of a grain of 'fine' gold, or in pence (at 2d. per grain of 'fine' gold) or cents per cubic yard or per ton? If reported per ton, should one cubic yard of ordinary damp alluvial, excluding boulders, be taken as equivalent to 3000 lb.? If not, what do you recommend?

3. Do you approve that in cases where money values are given for assays of silver, copper, tin, and other metals whose value fluctuates, the market price of a stated quality or brand of the metal, as taken for calculating such money value, shall be given, together with the assay value in ounces, etc., per ton, or in per cent or other concrete quantity?

4. Do you approve that in reporting assay values of cyanide or other solutions, results shall be reported in ounces or pennyweights, etc., in a stated *volume* of such solutions, or do you prefer the use of the ton of 2000 lb. instead of volume?

5. Do you approve that in reporting assays of silver and gold products and ores, the assayer shall state on his certificate whether the slags have been 'cleaned' and allowance made for cupel absorption?

6. Do you approve that all assay reports shall state the exact condition of the sample as to dryness, when assayed?

The above questions are merely given to facilitate the collection of opinions. Any additional suggestions, and criticisms on those outlined in the letter attached to this form, will assist the committee in arriving at a decision.

Atomic weights of certain common elements recently revised by a committee of the American Chemical Society are found to be as follows: Ag, 107.88; N, 14.037; K, 39.1135; S, 32.113; Pb, 207.19; Te, 127.609; Ra, 226.18. The Chemical Society (London) announces the atomic weight of Indium, printed in error last year, as being 115.00.

RECENT MINING WANDERINGS IN BURMA, CHILE, AND BOLIVIA.

Written for the MINING AND SCIENTIFIC PRESS
By J. H. CURLE.

On my way to inspect the property of the Burma Mines, Railway, & Smelting Co., I arrived in October of last year at Mandalay, in Upper Burma. Finding there the general manager, H. C. Hoover, and the manager, C. D. Clark, ready to start on the expedition we had previously planned, we got off without delay.

The genesis of the Burma Mines Co. was the discovery, in the vicinity of an old Chinese-worked silver mine, of dumps of lead slag. In 1904 these dumps were reported on by C. S. Herzig, who figured that they bulked about 115,000 tons, contained 48% lead, and were readily smeltable; hence the formation of the company in London.

Our expedition left the railway a few miles short of the small town of Lashio, its terminus. We were now in the Northern Shan States, the Chinese frontier lying some 40 miles to the east. Where we got off the Government railway, we saw the commencement of the 2-ft. line being built by the Burma Mines Co. to connect the Government railway system with the slag dumps, 50 miles north. We found the rails of this narrow-gauge line laid for five miles, and stretches of earthwork for 40 miles, but I could see that a good deal of work remained to be done. In the flotation of the Burma Mines Co. too little cash was provided for building the railway. This seems to be an initial error nowadays in all new mining ventures. In the present case, those in control no doubt thought that for a 2-ft. line, merely to run down 115,000 tons of slag, any sort of makeshift would do, and they provided accordingly. They forgot, perhaps, that the whole distance was through hilly country, and in dense jungle, and that for several months each year the road-bed and cuttings lie under torrential rains. These initial mistakes have cost the company a year's delay in reaching its slags, likewise the raising of £40,000 further capital for the more substantial completion of the line. The transport question, altogether, is the weak point here. The slags have to be hauled to Mandalay to be smelted. Assuming the Burma Mines Co. gets its 50-mile line in order after each rainy season, and delivers the slags at the junction, it is still in the hands of the Government railway, which must carry the material the 200 miles into Mandalay. But that concern is not yet equipped for hauling ore, and has intimated that it cannot handle more than 90 tons daily. As the smelter capacity at Mandalay is 200 tons daily, and as estimates were based on this quantity being handled, it is to be hoped that the Government of Burma will be induced to put pressure on the railway authorities.

After passing for some days through dense forest, we came out onto hill-tops, devoid, except for grass, of the slightest vegetation. For several miles around the old smelters, the Chinese had cut down every tree for fuel, and it seemed strange that though this was done many decades, or even centuries, ago, nature had not replaced the forest growth. This was Baudwen, 'the silver mine,' and in the valley below us we could see the dumps. This valley was at one time a prosperous Chinese mining republic. We found the ruins of a temple, and of rows of stone-built shops, and the remains of numerous small furnaces. Farther up the valley, landslides, covering many acres, point to where ore to the extent of millions of tons has been mined. Tunnels of more recent date have tapped orebodies on the confines of this caved ground; some of these carry fair lead ore, but they do not seem of great size. The extension in depth of the main orebodies will have to be determined by drilling; but whether this will show that the Chinese stopped because they had taken out all there was of value, or because of water trouble, I do not care to guess. At any rate, there is the chance of finding a mine, which, if it contains high-grade silver-lead ore, would be an asset after the slag-dumps have been beneficiated. Local tradition says the Chinese have not worked Baudwen for 60 years; then, perhaps, discontinuously. I should imagine the days of its splendor to have been several hundred years ago. The fact to grasp now is that there are some 55,000 tons of lead (in the form of 48% lead slags) lying in the valley ready to ship, and that the company expects to begin this work late in 1908. If lead is at a good figure for the next two years, it will make a large profit. The company has erected its own smelter at Mandalay. It will get coke from England and India, and has good fluxes locally. The transport question is the weak point, but it does not appear insuperable. With good prices for lead, and the finding of pay-ore under the old workings, the Burma Mines Railway & Smelting Co. ought to be a successful venture. It is certainly a deeply interesting one.

Report spoke of there being more slag-dump some 30 miles north of Baudwen, and I determined to examine these. Hoover and Clark having to return to Mandalay, I got W. A. Freymuth, one of the railway engineers, who speaks Burmese and Chinese, to go with me. The third evening we pitched our tent on Mo Ho Tchwang, the Chinese named mountain on the slopes of which the dumps were said to lie. Here, as at Baudwen, was evidence of old smelting work, for the upper part of the mountain lay bare of trees; we could see, too, on the other side of a steep valley, the outline of a big dump. Next morning we put a dozen natives to cut a path to this, through dense bamboo shoots 6 to 10 ft. high, and in the afternoon reached the dump—to discover it was all waste rock, evidently material rejected by those in charge of the furnaces. However, from this spot we could see a number of dumps lying on both sides of the valley, which really were lead slags, and in the course of four days, though not without much path-cutting and hard work, we found over 20 dumps. We also found several adits running into the mountain, into which we did not venture, but there was no 'caving' of big areas as at Baudwen. Many of the dumps were on the opposite side of the valley from the adits, a full mile distant, and higher up the slopes, and as they were mostly overgrown with vegetation,

it was no easy matter to find them. I figured by rough measurement that we saw not less than 50,000 tons of slag, and that there is probably more which we did not find. This Mo Ho Tchwang slag appeared to me to be one-third lighter than that at Baudwen. I took a sample back to Mandalay and arranged to have the analysis forwarded me to London. Subsequent cable advice gave the lead content at 25%, but I had left England again before the full analysis arrived. I think it probable that there is an excess of zinc in this slag, a fact which, combined with the low lead-content, will, I am afraid, cause it to be unpayable in that locality.

Leaving Mo Ho Tchwang, we traveled by mountain paths from one village to another, and after 120 miles reached Bhamo, on the Irrawaddy, whence I sailed by river-steamer to Mandalay and Rangoon, and so to England. I am not prepared to say that Upper Burma is to become a mining country. The slag-dumps of Baudwen and Mo Ho Tchwang are the only ones known, and it is doubtful if similar deposits of silver-lead-zinc ore, if found in those regions, would pay under present-day conditions. There is a little gold dredging on the Irrawaddy, far above Bhamo, but as yet with no real success; several placer areas are known in other parts; but Upper Burma is in no sense a rich goldfield. Forest and dense vegetation cover nearly the whole country, so that prospecting is hardly possible, while the lack of roads, and the remoteness of most of the country from rail or navigable river makes the transportation question most serious. A deadly malarial climate is another point for consideration; it nearly killed me before I reached Bhamo.

I got back to England on the last day of 1907. On January 16, 1908, I was off again—for South America—and in February, after crossing the Andes from Buenos Ayres, came to a short halt in Chile. That country I found in the throes of a financial crisis, brought about in part by the recent fall in metals, mainly copper. From one end of Chile to another copper mining has received a staggering blow, and from Chuquicamata on the Antofagasta railway to Cutter Cove near the Straits of Magellan, mines and prospecting ventures have been closed down wholesale. Chile is not fortunate at present in its mining. Some years ago a considerable gold dredging industry was started in the far south, and about a dozen dredges were installed, one or two on the mainland near Punta Arenas, the rest on the other side of the Straits, in Tierra del Fuego. But I believe I am correct in stating that not one of these dredges has earned a commercial profit, that most have run at a loss, and that this industry is slowly going the way of so many other dredging schemes. The most promising gold venture in these regions, if its Santiago directors can keep its finance sound, appears to be on Lennox island, 40 miles northeast of Cape Horn. Here, on the beach, a 10-in. suction-pump dredge has been built. The manager, A. Richardson, with Australian and New Zealand dredging experience, tells me he has proved at this spot 1½ million cubic yards of gravel worth 1s. 3d., and in another locality 4 million cubic yards worth 10d. When he starts work this will be the most southerly mine in the world.

Chileans, as a nation, are not fit to handle serious mining ventures. As practical mining men they are mostly futile, and their real interest in the industry begins and ends on the stock exchange. Last year a Bolivian tin mine, called Llallagua, was purchased by Chilean capitalists, floated in Santiago for over £400,000, and the shares were widely bought all over the country. This Llallagua, which I inspected some weeks ago, is probably the richest tin mine in the world at present. The Chileans, who, like the Bourbons, learn nothing from experience, sent a Chilean manager to control this venture. This worthy, for pure incapacity, would be hard to equal; for, though handling the richest tin mine in existence, with tin at a high price, he ran the company into a loss of well over £100,000. The enormous staff of Chileans under him were robbing the company at every turn. In desperation, the directors got rid of this man and appointed as manager an Englishman long resident in Chile, W. T. Holberton, late manager of the Copiapo Copper Co. His first act was to discharge 57 men from the staff, parasites of manager and directors (I am ashamed to say there was an Englishman among them), who were doing no work and were drawing fabulous salaries and commissions. In his first six months, with tin at lower prices, he has paid off £40,000 of the debt and developed big ore reserves. No doubt in due time he will free the company from debt, erect a decent concentrating plant, and start to earn large dividends. My only fear is that then the Santiago people will forget that a foreigner dragged them from the mine, will again place the company under Chilean management, and will re-start their stock exchange manipulations. Keep clear of the Chilean in mining matters, is my advice.

To get to Bolivia from Chile you must travel by the English-owned railroad from Antofagasta to Oruro. The distance is 924 kilometres, and the journey takes three days, traveling by day only. This line, with a 0.75 metre gauge, handles a big traffic. It runs through rich nitrate deposits, and beyond there is a great lake of borax—better than anything I saw in Death Valley, California. This is being worked on a large scale. There are also branch lines to several copper mining districts in Chile, and to the famous Huanchaca silver mine in Bolivia. This railway knows how to charge. Anthracite coal, for gas engines, costs £10 per ton in Oruro; the original price of machinery is doubled when it reaches here; and the freight on tin concentrate to the coast is £5 9s. 6d. per ton. The mining industry of the Bolivian highlands is largely at the mercy of this railroad, and it abuses its power. There is a continual block of freight-traffic at Antofagasta, and it frequently takes months to deliver anything after it has reached that port. Thefts, too, and losses, are common down there, causing serious delay and expense to the distant mine-owners. To this railroad also belongs the unenviable record of allowing its passengers to be provided with the filthiest food served at any railroad eating-houses in the world. Bad food, that is to say nearly all meat, and that

badly cooked, is the keynote of life on the Bolivian plateau. To make up for this, most of the English-speaking residents, who number several hundreds, drink inordinately, and many thereby come to grief. It is a country of crude methods. If you travel, you can only ride on mule-back, and over rugged mountain trails, carrying provisions, mattress, and blankets on a pack-mule, and covering 15 leagues a day. At night you turn into a mud hovel in some Indian village; at daybreak you are glad to be out of it and on the road again. The climate is good, with a rainy season from December to March. In winter the nights are very cold, although in the tropics. Oruro is 12,200 ft. high, and other mining towns range from 12,000 to 14,000 ft. Young men, coming from abroad, can stand this altitude, but a man over 50, or a man with a weak heart should not come to Bolivia. As is so often the case, where the conditions of life are unpleasant, the mines are rich. I had always thought Bolivia one of the richest countries in metals; now I have seen it to be so. With more railways and cheaper freights, this country would make a wonderful showing with its mines. At present Bolivia mainly subsists on tin mining, with an expanding output year by year, that for 1907 being figured at 16,600 tons pure metal. Huanchaca produces a lot of silver, and some comes from Potosi, Colquechaca, and Oruro. The Coro Coro district produces native copper. Gold is known in various places, especially on the lower eastern slopes, in unhealthy country, but apparently is being worked only in placers by the Indians. But tin is *the* metal in Bolivia at present. All other metals exist, probably in great quantity; but prices are low, transport bad, railway rates prohibitive, and no one thinks of prospecting for or developing anything else.

The tin lodes exist in a belt some hundred miles long, that is, from north of La Paz to near Tupiza. I believe that all of these lie higher than 12,000 ft., while Chorolque is 17,400 ft. and Santa Barbara is reported as over 18,000 ft.; the last being no doubt the highest mines in the world. I have no exact idea how many tin lodes are being worked in Bolivia, but it seems to me that for every lode already found, there must remain several unfound. For example, standing on the Llallagua mountain, in which exist several rich lodes, I saw, within the radius of a few miles, a dozen other mountains in each of which one would be justified geologically in looking for similar mineralization, although as a matter of fact in none of these is tin known to exist. There is no doubt that this district has been well prospected, not only by the Spaniards, who appear to have been thorough prospectors, but in recent years, since the discovery of the Llallagua mines. This raises the question of the existence of 'blind' veins in the Bolivian mountains, and as to whether it would be profitable to drive adits into many of these on the chance of striking lodes which do not outcrop. I am of opinon, so rich do I believe the mineralization of this belt to be, that such a course would lead to many discoveries, and that it is worth the serious attention of English and American capital. The tin lodes of Bolivia are as a rule of high value. From 5 to 15% of metal is not unusual, and from a number of mines a portion of the lode is shipped as broken, that is, it runs better than 60% metal. There are no accurate costs pertaining to this industry. These are only quoted as per ton of *barilla* (concentrate) recovered, and such items as the tonnage and value of ore in place, the number of tons treated each month, the quantity of slime produced, and the value of slime and tailing, are never procurable. Costs, in any case, are necessarily very high. Indian labor is not too plentiful, but is good. Feast days and bouts of drinking excepted, the Indian puts in good work, and receives from $1 gold per day upward. Supervision is carried on in some mines by Bolivians, in others by Europeans, Cornishmen predominating among the latter. From all the bigger mines the ore is shot down by aerial ropeways, some of these being four to five miles long, and costing on an average £1 10s. per yard to erect; they appear to work well. Except just around Oruro all the crushing and concentrating plants have water, although this is, in places, scarce and used by several plants in succession. Concentration is usually preceded by crushing in stamps or ball-mills, followed by jigs and buddles. Wilfley or other tables are used in some plants, and in others they have been thrown out as being too delicate to be handled by Indian operatives. Hand-jigging and buddles constitute the favorite method; this is primitive, and requires an immense amount of re-handling, but with conditions as they are, is not so ineffective as one might imagine. A lot of slime is produced—possibly 30%. This is usually put over buddles, and the assumption is that half its tin content is recovered. I know of no mine doing any systematic sampling, either of slime or tailing, and cannot give figures as to losses in treatment; but no doubt the loss is not less than 30% of the total tin content. The concentrates vary from 55 to 70%, averaging just over 60% of metal; these are all shipped to England; anything below 62% is penalized by the smelters, and on a *barilla* of only 50% the penalties are almost prohibitive. From a mine close to Oruro, consequently on the railroad, the costs of realizing a ton of *barilla* work out as follows:

	£	s.	d.
Bags and bagging	0	16	6
Freight to station	0	11	0
Sundries at Oruro	0	1	10
Export duty (with tin at £140)	2	16	3
Rail to Antofagasta	5	9	6
Agency, etc., at Antofagasta	0	9	9
Freight to London	2	15	0
Insurance, agency, assays, brokerage, commission, and smelters, incidentals	3	10	0
Returning charge (for 62% *barilla*)	11	15	0
	28	4	10

From a mine situated far from the railroad a transport cost of several pounds per ton would have to be added to the above. The cost of producing concentrate varies too much to be included, but is on the same heavy scale. Bolivia is fortunate

in so far that its average tin mine is rich, and that tin keeps a good price, otherwise working and transport costs would be prohibitive. The key to the situation no doubt lies in the fact that the richer ground in the Straits Settlements is mostly worked out, and that the cost of producing tin there is going up all the time. There are still immense areas to be worked in the Straits, but it is believed that the produeing costs will be such that the market price of the metal will average more in the future than in the past, and that it will not again fall below, say, £120. It is a dangerous thing to prophesy metal prices, and I have no opinion on this point; the belief just expressed is that current among the mine-owners.

The most interesting mining field in Bolivia is the famous mountain of Potosí, rising to nearly 16,000 ft., or 2700 ft. above the considerable town lying at its base. Native silver was discovered here by an Indian, in 1545, and when the butcher, Pizarro, was building Lima, in the earliest days of Spanish occupation, his hatter was sent to extract wealth from these already celebrated mines. Here is still to be seen the Royal Mint, now in use by the Bolivian Government, and its wonderful wooden machinery of former days. The Spanish Government annexed 20% of all the metal as royalty and then for hundreds of years an increased revenue from this mountain. Potosi is covered with the dumps of hundreds of workings, and its interior is even yet a net-work of veins. Silver is worked to a small extent still, but tin mining is the chief industry. The Indian miner of Potosi, working 36 hours at a stretch, does his work on contract, receiving payment relative to the value of the ore he produces. I was told that he receives one-half the value; this seems hardly credible, but whatever the figure there is no doubt that the mining cost to the owners is enormous. Then there is transport. Potosi is 150 miles from the railroad, over many mountain ranges, and freight thither is about £5 10s. per ton. Coal being prohibitive, *gareta*, a native moss, is used for fuel, while charcoal costing £6 per ton comes from the interior.

To lighten cost of transport, some crude smelting is done at Potosi in small water-jacket furnaces. Tin bars, of 92%, are thus produced, the balance being lead, antimony, etc., and despite the cost of fuel a saving is made by shipping these bars rather than concentrates. Tin is being mined profitably at Potosi, by adits, at nearly 2000 ft. vertical below the summit, and may extend deeper. The geology of the lower part of the mountain, however, seems obscure; it is not yet penetrated by any deep workings. Leaving this in doubt, there must still be a vast quantity of silver and tin ore unexplored, or left behind from richer patches. But the titles to mines on the mountain are in a shocking condition, and the whole of these would have to be brought under one corporation, and that given a fresh title by Government, before foreign capital could come in here. Given such a consolidation of the Potosi areas, and a railroad, this mountain might again emulate its past records. Failing these factors, it will remain a field of many small enterprises, severely handicapped in its economic conditions.

There is as yet little evidence concerning the value of Bolivian tin mines at depth. As has been mentioned, those in the Potosi mountain carry their values down, but nowhere else have they been tapped so far below the outcrop. Most of the other mines are shallow, say less than 600 ft. deep, and appear to be still holding their value in the bottom. Sulphide ore is showing in a number of mines, which require calcining previous to milling, and as there seems to be no impoverishment in the sulphides I should say that the evidence of ore lasting to moderately good depths is favorable.

Bolivian politics are not inimical to mining, for the chief families of the State have made their wealth from mines, and this is the main industry of the country. The weak spot is the question of title, which may arise from original mistakes on the part of improperly qualified surveyors, or perhaps from the acts of corrupt officials. Many of the best mines are continually troubled by law-suits, and the courts are always full of cases dealing with validity of title. No doubt, with care in the beginning, and the services of an influential lawyer, much of this trouble over titles could be avoided. The worst feature in connection with Bolivian mines, from my point of view, is that they carry no ore reserves, the British-owned mines in this respect being as bad as those owned and run by natives. Llallagua, certainly, has a good reserve, but this is exceptional. Notwithstanding this lack of ore in reserve, the mine-owners won't sell under 10 years' purchase, and during the 'boom' of last year several were fortunate enough to get out on this basis to fool companies floated in Chile. It is useless going to Bolivia with the idea of buying a developed mine, for the careful mine-valuer will never see his way to offer more than one-quarter of the price demanded by the owner. Last year, when tin was booming, representatives of the Steel Trust and the American Smelting & Refining Co. scoured Bolivia for tin mines. Of course, they did no business; for they were men with reputations to lose, and they did not see their way to risk 80% of the purchase price in non-visible ore, and it will always be the same there. The best way to secure mines in Bolivia is to take up absolute prospects, or to drive adits in the hope of striking blind veins. If I could only stand the discomforts of the country, I would do this myself, for I am convinced of its great wealth—both found and unfound.

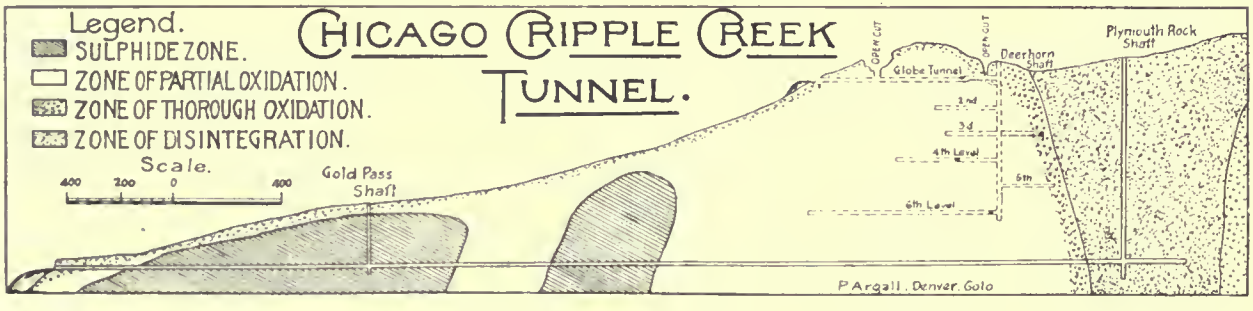
Silica is constantly being added to or subtracted from rocks within the zone of meteoric waters. Alteration is always progressing, unless there is entire absence of moisture. All meteoric waters contain carbonic acid, which comes nearer being a universal solvent than any other common substance. The solvent effect upon silicates is increased by carbonate of ammonia, which is always present in waters derived from rainfall. The process of dissolving silica from silicates is called carbonation, because the carbonic acid takes the place of the silica in combination with the bases.

ROCK OXIDATION AT CRIPPLE CREEK.

Written for the MINING AND SCIENTIFIC PRESS
By PHILIP ARGALL.

The deep and thorough oxidation of that portion of Globe hill extending in a southeasterly direction from the Summit shaft to about 100 ft. beyond the Plymouth Rock shaft, has received almost as much attention from geologists as that unique deposit of gypsum exposed in the Deerhorn shaft, forming, as it were, the core of this great area of oxidized and disintegrated breccia. The following description of the occurrence culled from extensive notes made during an examination of some Globe Hill properties in 1905 may prove of some interest in the study of thermal action and oxidation of rock-areas. It is a matter of regret that on account of the numerous caves in the deeper levels of the Deerhorn mine I was unable to obtain complete data, more particularly as to the extent of the gypsum deposit along its strike southeastward.

The oxidation of the breccia and other wall-rocks of the Cripple Creek district is seldom referable to the water-level at any given place, but is solely attributable to the facility offered for the circulation of meteoric waters in the joint-plane, cracks, incipient fissures, and veins in the rock-mass. This is clearly seen in the section of the Chicago & Cripple Creek tunnel. Taken in connection with the thorough oxidation of the breccia at the Deerhorn, and its disintegration and reduction to a mass of soft clay, this section affords an interesting study in rock oxidation and decay.



The portal of the Chicago & Cripple Creek tunnel is situated in Poverty gulch, close to the Abe Lincoln mine, at an elevation of 9700 ft. The adit starts in a thin band of schist passing in a short distance into the massive unoxidized breccia, which I shall, for distinctness, designate the 'sulphide zone.' In this zone the breccia contains pyrite in considerable quantity, well distributed throughout the rock. Where veins occur, pyrite is the principal mineral and it appeared to me that there was also a heavier impregnation of sulphides in the wall-rocks of the veins, but even where no veins appear, the joint-planes of the rock were covered with films of fine sulphides, mostly pyrite. This sulphide zone may be considered the unaltered breccia of the district, it is the prevailing rock in which the sulpho-telluride veins occur, and it is assumed to have passed through no particular change or alteration since the formation of the veins and the deposition of the ore.

About 1400 ft. from the portal the adit passes out of the sulphide zone and enters one of partial oxidation, simply the same breccia with open slips, or joints, small fissures, and shattered zones through which circulating waters oxidized the exposed rock-faces, often filling the larger open joints and small fissures with iron and manganese oxides. Where the rock is shattered into small fragments, the oxidation may be complete; usually, however, a piece of rock no larger than a man's fist when broken open shows a core of blue unaltered breccia with shining pyrite. This I shall designate the 'zone of partial oxidation.' It, of course, passes gradually over to the zone of complete oxidation when the pyrite in the rock-mass is all oxidized and the whole rock stained with iron and maganese oxides, either or both. Near the surface this rock is soft, but stained throughout with oxides and never shows the greenish blue of the breccia or phonolite groundmass. The zone of partial oxidation in the average Cripple Creek mine is usually reached at depths varying from 20 ft. to 150 ft. from surface, depending on the permeability of the rock-mass. The Chicago & Cripple Creek tunnel passed through 240 ft. of this zone of partial oxidation and again entered the sulphide zone, through which it passed for a distance of 400 ft.; here copper sulphate was detected in several places on the tunnel-wall resulting from the oxidation of sulphides since the adit was opened. An examination of the rock near one of the copper colorations revealed crystals of chalcopyrite, the first I had seen at Cripple Creek.

Emerging from the 400-ft. sulphide zone, the adit enters a second zone of partial oxidation, which was penetrated for a distance of 1500 ft. at an average depth below the surface of some 700 ft. (see section), but gradually becoming more oxidized; the next 100 ft. of the adit is in the thoroughly oxidized zone; next comes that peculiar product of Globe hill, a thoroughly oxidized and disintegrated rock which I shall designate the 'zone of disintegration.' At the time of my examination the tunnel was caved at a point slightly beyond the Plymouth Rock shaft after penetrating the latter zone for a distance of 120 ft. From the best information obtainable at the time, it appeared that the Plymouth Rock shaft had been sunk about 800 ft. in this loose disintegrated material, terminating about 60 ft. below the floor of the Chicago tunnel, the then water-level of this locality, and in the same loose material.

The disintegrated breccia around the Plymouth Rock shaft at the Chicago tunnel horizon is quite loose and soft, not unlike material that had filled a cavity. It contained much iron and manganese oxides.

some rounded lumps of kaolin, a little gypsum, and occasional pieces of barite; in places manganese oxide predominates and the material is not unlike a pile of loose ashes. The red oxides of iron so common in the upper workings of the Deerhorn are not plentiful at this depth, brown and black colors predominating.

We can now summarize:

(1) Sulphide zone.—The practically unaltered rock.

(2) Zone of partial oxidation.—The rock mostly oxidized on the faces, joints, cleavages, and fissures.

(3) Zone of thorough oxidation.—The pyrite all oxidized and the rock softened and stained with oxides, none of the original color being left.

(4) Zone of disintegration.—Rock thoroughly oxidized and disintegrated, reduced in fact to ferruginous clays and talc.

This last zone extends for a length of about 1000 ft. in a southeasterly direction from the Summit shaft to some distance beyond the Plymouth Rock shaft and Chicago & Cripple Creek tunnel. The distinguishing feature in the Summit workings is the great amount of kaolin, resulting from the decomposition of the feldspars, and its accumulation in the veins, fissures, and channels of disintegration. The pay-veins of the Summit mine occur in the zone of thorough oxidation and when followed southeasterly they disappear in the zone of disintegration near the boundary of the Deerhorn claim.

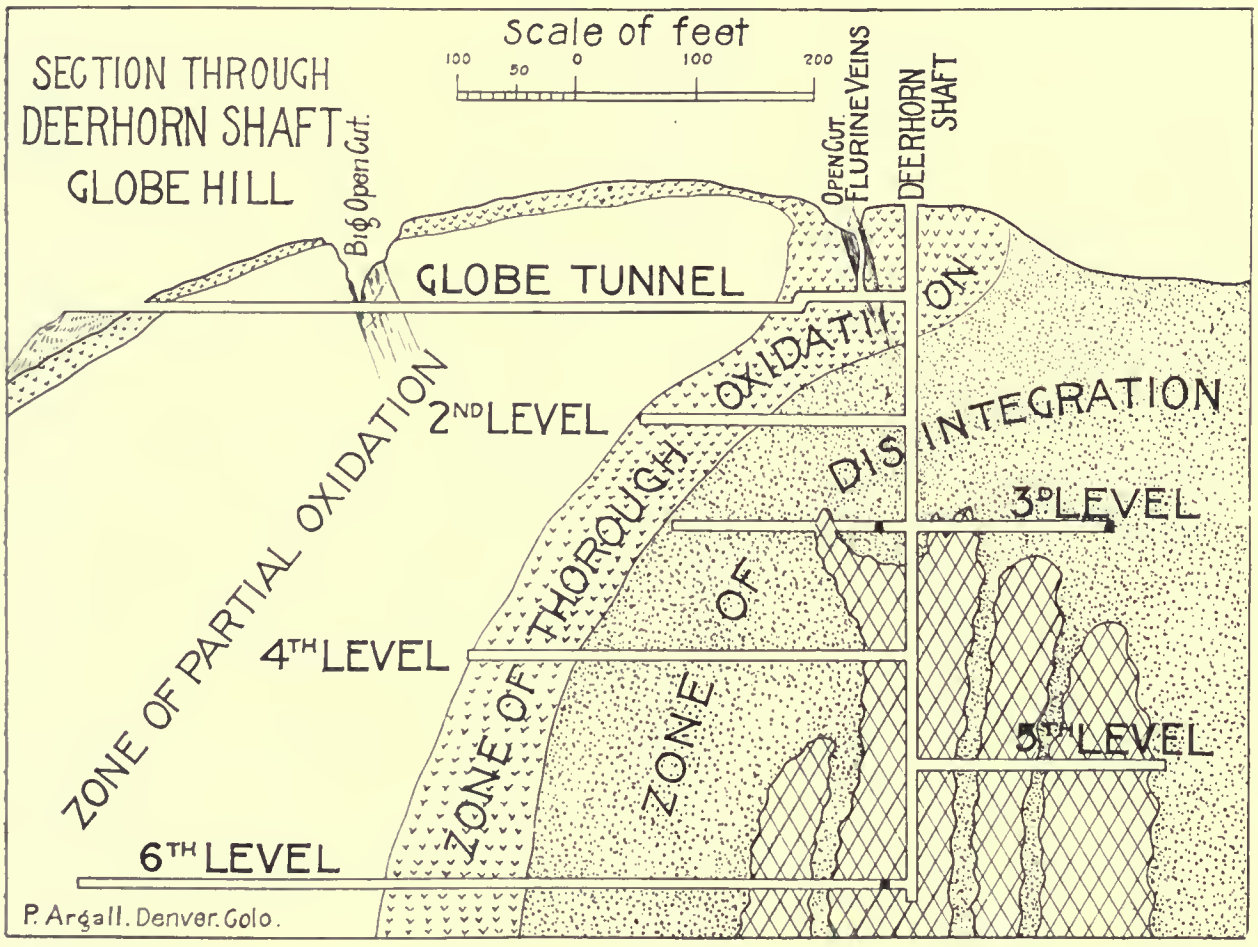
On referring to the section through the Deerhorn shaft, it will be noticed that the zone of thorough oxidation extends to about midway between the first and second levels; in this rock, well defined pay-veins occur in which pink fluorite is the most striking feature. The open-cut contains two such veins with numerous interlacing branches of almost solid fluorine and granular quartz filling. They show an average regularity in dip and strike, making allowance for the usual vagaries of Cripple Creek veins, and they have been, on the whole, fairly productive. On entering the zone of disintegration, however, these veins are extremely difficult to follow, they contain little value and as a rule speedily disappear in that soft heavily ironstained material forming the zone of disintegration.

On the third level of the Deerhorn shaft, three tongues of massive crystalline gypsum occur, apparently of great purity though surrounded by dark reddish and brown clays, kaolin, and other products of rock decomposition. The gypsum is quite white and contains numerous bunches of crystalline pyrite, some of the cubes having quarter-inch facets, there are also some minute pyrite crystals disseminated in the mass of the gypsum. In places, fluorite occurs in sufficient quantity to give the rock a pinkish tinge: galena and other sulphides occur in occasional minute crystals disseminated in the gypsum; the outer boundary of the gypsum is everywhere corroded and plainly shows the action of some solvent, possibly water, about 400 parts of which will dissolve one part of gypsum, and with sulphurous acid present in solution this rock would be still more soluble. Thirty feet below the third level, the Deerhorn shaft passes into a solid mass of gypsum and continues therein to the bottom, or sixth level. The western limit of the gypsum deposit is clearly determined by the westerly cross-cut on the fourth level, as is also the limit of the zone of disintegration. The eastern limit of the deposit is shown on the fifth level, where the station is cut in the east side and a cross-cut extended easterly through the gypsum; there are no workings on the west side, but by constructing the western limits from the fourth and sixth level exposures, the gypsum would appear to be about 240 ft. thick at the horizon of the fifth level. The east cross-cut on the fifth level intersects two pipes, water-courses of oval shape, the longer axis being at right angles to the plane of section. These pipes had been at least partly filled with the loose ferruginous clay that surrounds the gypsum deposit in the zone of disintegration. The timbers of the level having decayed and broken down so as to allow the contents of the pipes to cave to a considerable extent, I was enabled to pass into some of the pipes and examine them closely. They appear to be openings along lines of fissuring and were water-conduits of some sort, though now dry as a bone and quite warm. While it is possible these pipes may have been formed by the solvent action of descending waters—and there is strong evidence of such action—yet they so strongly resembled in form of crustification and in general appearance, the pipes of thermal springs I had seen in New Zealand that I had no hesitation in believing them to be of similar origin, though in places enlarged and changed by re-solution of the gypsum since the close of thermal activity and the lowering of the water-level of the district permitted the descent of surface waters in the pipes of the original hot springs.

The sixth level (575 ft. from surface) is the bottom of development in the Deerhorn mine; no work had been done in an easterly direction, while the west cross-cut was (at the time of my visit) caved at about 60 ft. from the shaft and the level filled with reddish earth, whether from a pipe or the outer boundary of the gypsum I could not determine. Rickard, however, calls attention[1] to an outlier of gypsum at this point, which he examined while the original development was in progress. This is my authority for the western column of gypsum on the sixth level; the eastern wall of the pipe was, however, exposed for some height above the level and appeared in every way similar to those I had the opportunity to examine. A drift extended 50 ft. southerly from the station (along the strike of the deposit) through solid gypsum. At this point another pipe is revealed; it also was filled with reddish clay which had in part caved, closing the level, but permitting a complete examination of the pipe for 30 ft. above; it looked like a water-course. My note reads: "It is truly water action that has dissolved this space in the gypsum, which is simply a water-course filled with red ash and debris from above, brought down from the oxidized ground surrounding the gypsum." The study of the other pipes

[1] T. A. Rickard, 'The Cripple Creek Volcano.' *Trans.* A. I. M. E. Vol. XXX, p. 399.

led me to the conclusion that they were first thermal conduits, afterward enlarged in places by the solvent action of descending waters. All the workings described on the sixth level are in massive gypsum of varying purity, that at the bottom of the shaft is white and crystalline, shading toward pink in places, possibly from the presence of fluorite; no bedding structure could be observed; very fine pyrite crystals are disseminated all through the white gypsum, while the impure variety contained some dark sulphides, mostly pyrite, on the joint-plane and surrounding pieces of altered breccia. West of the station the rock has the appearance of a fine breccia saturated with, and cemented by, gypsum differing much from the white variety at the shaft. This



gypsum rock stands quite well even without timbers, it does not appear to soften or slab in the least. The workings were dry and the temperature I would judge at about 80° F.; on account of the caves there was no circulation of air, nor was there any accumulation of carbonic acid gas so prevalent in other mines in this vicinity.

At the time of the geological examination of the Cripple Creek district by Cross and Penrose, developments in the Summit mine had reached a depth of 200 ft. and in the Deerhorn 280 ft.[2] In discussing the evidence of fumarole action Cross says: "Gypsum occurs in the Deerhorn mine on Globe hill, in ore veins, and is most probably the result of aqueous action." Penrose considers the gypsum "possibly, though not necessarily, the product of the action of sulphuric acid or sulphates derived from the oxidation of sulphides on carbonate of lime or other calcium compounds derived from the alteration of certain eruptive rocks." Regarding the occurrence of the gypsum, this observer states: "In a vein on the 280-ft. level of the Deerhorn mine considerable quantities of a compact, fine grained crystallized gypsum, containing more or less fluorine, occurs; while on some of the upper levels thin layers and crystals of gypsum are found in the cracks in the breccia." Rickard, in speaking of the Deerhorn gypsum deposit, says: "There can be no doubt as to the nature of these masses of gypsum. Thermal springs that have become extinguished are marked by just such accumulations of lime, although the carbonate is, under such circumstances, more common that the sulphate. The flow of hot water encountered in the deep workings of the Comstock carried a notable percentage of gypsum." Lindgren proves[3] the presence of sulphates in the circulating water during ore deposition, by the "almost universal occurrence of celestite or sulphate of strontium in the veins, as well as by the more sparing development of barite. . . . Calcium sulphate is not found as a primary constituent of the veins, but the peculiar occurrence of large masses of gypsum associated with pyrite and fluorite at the Deerhorn mine, leads to the belief that waters rich in sulphates of the alkaline earths appeared as one of the latest phases of thermal activity. The closest analogy to this would perhaps be found in

[2] 'Geology and Mining Industries of the Cripple Creek District.' Washington, 1885.

[3] 'Geology and Gold Deposits of the Cripple Creek District Colorado.' Professional Paper 54. Washington, 1906.

the hot waters of the Comstock lode, which are exceptionally rich in these constituents." It appears that the lower levels of the Deerhorn were not accessible during the examination of Globe hill by Lindgren and Ransome, who quote from Rickard's description of the gypsum deposit and zone of disintegration. Regarding the latter, we find on page 197: "The explanation of this unusually deep oxidation is probably that extensive shattering preceded a local and very intense thermal-spring action, which by dissolving much material rendered the breccia so porous as to fall an easy prey to oxidizing processes." The gypsum in "the Deerhorn mine is, however, probably not formed during oxidation, but is more likely a primary deposit by hot waters."

The authorities quoted are in agreement that the gypsum deposit is the result of thermal-spring action occurring toward the close of volcanic activity; it must be noted, however, that pyrite and fluorine were deposited with the gypsum and very probably throughout the space now represented by the zone of disintegration. Gypsum is of common occurrence in sulphate springs, hot and cold. Flourite has also been detected in thermal springs of low temperature, as, for example, the mineral springs of Schwollen, in the Duchy of Oldenburg, to the extent of 0.0005 gram per litre, and at those of Baden to the extent of 0.0021 gm. per litre, while the deposit from the Sprudel water at Carlsbad gives practically 1% calcium fluoride.[4]

The source of the gypsum on Globe hill is probably from below, that is, from a greater depth than is revealed by any workings today; as a possible source of sulphate waters, Gautier has shown[5] that granite heated in a sealed tube with water to a temperature of 250 to 300°C. yields sulphur compounds in solution, resembling the sulphur waters of hot springs. He ascribes the sulphur to reactions on sulpho-silicates such as haüynite and lazurite, and not to metallic sulphides. This conjecture is interesting; from the granite could be obtained both the gypsum and the fluorite, as it is well known that fluorine compounds are specially characteristic of plutonic rocks, and, indeed, it has been recognized in Cripple Creek granite. The enrichment of the zone of disintegration by iron and manganese oxides remains to be considered. The composition of the average rock of the Cripple Creek volcano is computed by Lindgren at about 3% mixed ferric and ferrous oxides. Practically all of the spongy rock-mass in the zone of disintegration is heavily saturated with iron oxide; some of it is almost a low-grade iron ore. Where, it may be asked, did this great quantity of iron come from? It saturates a channel of porous rock about 1000 ft. long, perhaps a similar depth, and, say, 600 ft. wide, all of which contains much more iron and manganese oxides than the average oxidized mineral veins of the district. Two sources suggest themselves: one by descent from oxidation of the superincumbent breccia, since removed by denudation: secondly, from the oxidation of pyrite deposited in the altered breccia itself, say, at the beginning of solfataric action. I am rather in favor of the latter hypothesis. It must not be forgotten that gypsum is much more soluble than celestite and may easily have been leached out of the veins by circulating solutions, hence, the possibility of the closing period of vein formation being coincident with solfataric action, at Globe Hill, for example, where the simultaneous deposition of pyrite, galena, fluorite, and gypsum affords at least some evidence in favor of such phenomena. It may be claimed that the gypsum deposit is a local occurrence, and to a large extent it is, for I take it that the sulphate solutions that built up the great mass of gypsum rose along lines of fissures, dissolving and replacing the breccia in their neighborhood. I could not conceive a cavity representing the proportions of the gypsum deposit remaining open during the long period necessary for the deposition of the gypsum mass; furthermore, we have in the partial replacement of breccia in the gypsum at the sixth level what I take to be direct evidence in favor of a replacement process.

The periphery of the gypsum deposit, at the few places where I could examine it, showed strong evidence of partial solution; at such places it is surrounded by very loose iron oxide conforming to the configuration of the gypsum, while the latter is pitted with numerous cavities and corrugations, but is quite solid, showing no graduated passage from the solid gypsum to the decomposed breccia; hence I believe the deposit was much larger before the period of oxidation set in, and also extended much higher than the present section shows; the peculiar fin-shaped pieces exposed on the third level are in themselves evidence of solution.

The phenomena of volcanic action and rock oxidation on Globe hill suggest the following tentative cycle of events:

(a) Fissuring of the breccia and general shattering of the rock in the main channel, followed by fumarole action with kaolinization of the feldspars, closing with the deposition of minerals in the veins and pyrite in the partly decomposed breccia; this is perhaps more correctly classed as the early solfataric stage.

(b) Solfataric stage, deposition of gypsum, pyrite, etc., from sulphate waters along lines of fissuring, and, in part, in the spongy breccia of the shattered zone, closing with thermal waters rising in pipes to the then surface of the ground, said pipes being somewhat centrally placed in the mass of gypsum.

(c) Oxidation period. Descending meteoric waters dissolve the upper portions of the gypsum and the less solid portion around its periphery and to some extent enlarging the pipes of the original springs. At the same time, the pyrite in the shattered breccia channel was oxidized, completing the disintegration of the rock and forming the zone of disintegration as we now see it, much of the iron, of course, was removed in solution, but enough remains to show that at some time this great channel was, as I take it, very thoroughly impregnated with pyrite.

MINING CLAIMS ON FOREST RESERVES.

By the courtesy of Mr. Horace V. Winchell we are able to present a draft for a memorial to Congress submitted for the consideration of a committee on the revision of the mining law of the United States appointed by the Montana Society of Engineers. Mr. Winchell remarks that "it voices the complaints which are now becoming very common against the present system of inspection of mining claims located under the mineral land laws of the United States. I am aware, from personal inspection, of injustice in a number of cases, and I am convinced that the present method is extremely faulty." The memorial recites:

In the State of Montana, practically all of the mountains have been set apart as National forests, leaving only the bare bench and valley lands open to appropriation under the agricultural laws. Since the mountain districts are practically the only regions where mines are exposed, it follows that these reserves include nearly all of the territory in the State of Montana upon which a prospector can look for mines. Congress has enacted that mines may be located upon National forests as elsewhere. And if this law were interpreted by the officers of the Land Department in accordance with its spirit, we should have no complaint to make, but it is interpreted in so narrow and suspicious a spirit as to make it exceedingly difficult and in many cases impossible to secure patents for mining claims upon forest reserves. In a little book entitled 'The Use of the National Forests,' by Gifford Pinchot, Chief Forester, a book intended for the reading public, the following directions are given under the head 'Prospecting and Mining': "Proceed just as on the open public domain. National forests do not interfere with these matters at all." These sentences, we maintain, are misleading, for, as a matter of fact, a miner on a forest reserve cannot proceed just as on the public domain, and it is not true that National forests do not interfere with the development and acquisition of title to mining claims. In the 'Use Book,' consisting of regulations and instructions for the guidance of the officers of the forest reserves, such minute and exacting requirements are made in regard to the examination and tests of mining claims by the forest officer as to make it a very exceptional and rare prospect indeed that will pass the scrutiny. The officer must measure the width of the vein, sample each grade of ore, carefully wrap and label the sample, place it under lock and key to prevent 'salting' and in the event of a contest or adverse report by the inspector, he must send it to the assayer of the mint at Denver, Carson City, or Seattle to be assayed. Upon the basis of this investigation, the officer decides whether or not the claim is of commercial value. If not of commercial value, nor capable of being made so immediately, the claimant's application is rejected.

The laws of the United States permit a claimant to apply for and secure patent after the expenditure of $500 worth of work upon a mining claim. The Courts, both Federal and State, have held that in the absence of an agricultural contest for the land, small evidence of actual ore-value need be shown in order to uphold a mining location. It is a rule practically universal in the Courts that if the vein or lode located is such as to justify a person of ordinary intelligence in following up the indications of ore, and in expending his time and money in its development, it affords a sufficient discovery to justify and uphold the location. But the officers of the Land Department require very much more stringent tests. They apply such tests as are applied to a fully developed and marketable mine.

These tests are unauthorized by law, entirely unreasonable, and unduly exacting, and have been formulated by some person or persons who are ignorant of the conditions of ordinary mining. Such tests have never been applied before in the history of mining in the United States. The laws of the United States require only $500 worth of work to be performed or improvements to be made upon a mining claim before one may apply for patent. When these improvements have been made, if he has a vein such as the Courts have held sufficient to justify the location, he is entitled to a patent under the laws of the United States, whether the claim be situated upon a forest reserve or elsewhere. The officers of the National forests have formulated rules practically nullifying the laws of Congress, and with which it is almost an impossibility to comply, notwithstanding the entire good faith of the applicant. Five hundred dollars does not go far, as a rule, toward developing a paying mine, and after the expenditure of that sum it is a rare mine indeed that will respond to the tests required by the officers of the Land Department. We speak from knowledge when we say that the great Anaconda mine in Butte would not have responded to these tests. The same is true of the St. Lawrence, Mountain View, Rarus, Minnie Healey, Speculator, and many other mines in Butte that have produced millions, the names of which are familiar to people throughout the mining world.

It requires a mining expert of rare judgment and foresight to determine the prospective value of a mining claim, and even men of the highest qualifications in this respect sometimes find that their unfavorable judgment of a mining claim has proved erroneous and short-sighted. The Land Department does not employ men who are entitled, if judged by ability and experience, to be called mining experts, yet the value of a prospector's claim is at the mercy of the judgment of these pseudo-experts. It is true that the claimants can appeal, but appeals are expensive, and cause much delay and annoyance, even though it should eventually be proved that the locator has acted in entire good faith. The Supreme Court of the United States has held that the officers of the Land Department are the final judges as to the character of the land, and from their decisions, based upon the testimony of their mineral experts, there is no appeal.

Even where a special agent approves a mining claim, his very approval seems to be regarded with suspicion by his superiors, resulting often in the sending of a second special agent to examine the

same mining claim, and resulting in long delays and often the ultimate refusal to permit the mineral entry of the claim.

The entire administration of the Land Office in the State of Montana seems to be permeated with the spirit of suspicion and espionage. This spirit also fosters and causes opportunity for blackmail. Claimants who have been defeated in the courts in a mining contest carry their grievances to the special agent, making charges of insufficient work by the adverse claimant, or lack of good faith in some other respect, and the special agent is in a position to suspend action upon the application until it shall have been subjected to a hearing before the Land Office.

There is another grievance which mineral applicants have against the present administration of the law, that applies not only to National forests but to the open public domain as well. It often happens that shafts and tunnels representing part of the $500 worth of work have caved when application for patent is made, or cuts and bed-rock drifts in placer workings have washed full of gravel during the spring freshets, so that they are inaccessible. Hitherto it has been the custom of the Land Office to require the affidavits of two disinterested witnesses, conversant with the facts, as to the character and extent of these improvements. But recently the affidavits of such witnesses have been dispensed with. A special agent, furnished only with the published notice of application for patent, which does not go into the details of improvements or their application, now goes upon the ground without any notice to, or assistance from, the applicant. The claimant's point of view is a matter of utter indifferenee with him. If a 50-ft. shaft has caved to within 10 ft. of the surface, the special agent reports a 10-ft. shaft only. If placer workings have washed full of gravel, he reports no improvements found. If a 100 or 500-ft. shaft has been sunk to represent a group of claims, he reports this work on the claim upon which the shaft is found, and reports adversely upon the others. In the book above referred to 'The Use of the National Forests,' Mr. Pinchot says: "National forests exist today because the people want them. To make them accomplish the most good the people themselves must make it clear how they want them run." This invitation to the people is an invitation to mining men everywhere to offer suggestions as to how the mining laws of the United States should be administered upon the National forests and upon the open public domain of the United States, and it is in order for them to consider the matter and formulate such suggestions.

Copper-Leaching Process.—O. Frölich, in a paper recently read before the Elektrotekniscne Verein, proposes, instead of roasting the ore, to heat it to about 800°C. in a retort furnace out of contact with air. One-fourth of the sulphur distils over as such, and the ore itself is disintegrated so that it can easily be lixiviated with a solution of ferrous chloride and common salt. This operation is hastened by mixing by means of a screw mounted vertically in a steam-jacketed vat.

AN INTERESTING TELEGRAM.

It is our privilege to present an exact copy of the telegram on which the Tonopah mine, now owned by the Tonopah Mining Co., was purchased. It is a document of historic interest in the annals of mining, representing a case in actual life of estimating available ore of fabulous value while the property itself remained a mere prospect. The realization of this sort of wild dream in which the prospector indulges, and which the promoter heralds to the world, seldom comes. In this instance it did.

Reno, Nevada, June 5, 1901.

Hon. John W. Woodside,
931 Chestnut Street,
Philadelphia, Pa.

Tonopah mines greatest surface showing ever discovered. Thirty-seven holes on eight claims producing both milling and shipping ore. Many others producing fine milling ore, all being worked by tributers. Net profits to owners one thousand dollars daily on ore shipped; have bought these eight claims for three hundred and thirty-six thousand dollars. Fifty thousand payable June 28th. One hundred thousand October 1st, and one hundred and eighty-six thousand December 20th. Have drawn on you for first payment. Draft due at Penn Bank, Philadelphia, June 28th. Under my agreement, tributers may work their ground until December 31st, but all royalties received by owners after June 1st, to be applied on purchase price and to be subtracted from our last payment. We may enter upon any part of ground, and mine after meeting first payment. At least one million dollars in sight above fifty-foot level. Deepest shaft seventy feet, vein there six feet. Five feet forty dollar rock one foot three hundred dollar rock. Eighty thousand to one hundred thousand dollars worth of forty dollar milling rock now on dumps. One-fourth of this and one-fourth of all mined hereafter comes to us and we can ask all we want for milling other three-fourths owned by tributers or buy them out at our own figure when reduction works are ready. Will mail full particulars in few days. You must get the money to meet this draft without fail. I cannot get the time extended. Wire me at Grass Valley.

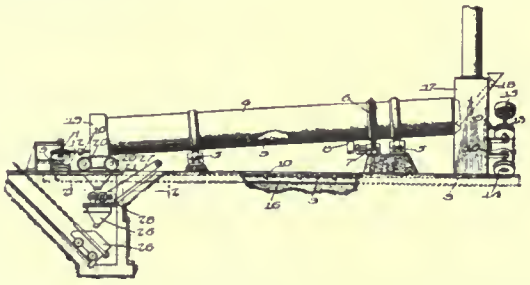
(Signed) O. A. Turner.

Coal value, estimated in terms of heating power expressed in British thermal units, is becoming the basis of sale in England, instead of quoting so much per ton. Contracts are made to deliver a certain number of B. T. U. per penny, varying from about 270,000 to 320,000 moist, or 290,000 to 343,000 dry. The calculation, according to J. B. C. Kershaw in *Cassier's Magazine*, is made by the following rule: multiply the number of British thermal units per pound of dry coal by the percentage of moisture, subtract the product so found from the total number of B. T. U. per pound of dry coal, multiply the remainder by 2240, and divide this product by the contract rate per ton (expressed in pence), plus one-fourth the ash percentage. Payment is adjusted to the actual number of heat units delivered.

MINING AND METALLURGICAL PATENTS.

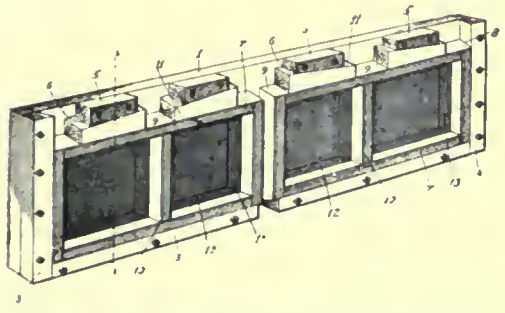
Specially Reported for the MINING AND SCIENTIFIC PRESS.

METHOD OF PREPARING ORES FOR USE IN THE MANUFACTURE OF STEEL.—No. 887,379. Eugene B. Clark, Chicago, Illinois.



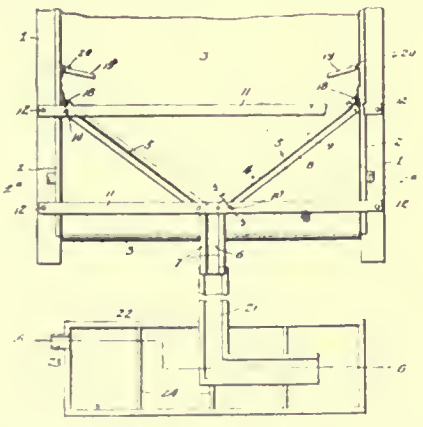
The method of treating fine ores for the purpose described, which consists in passing the ore through a substantially horizontal cylindrical kiln wherein it is reduced to a semi-plastic condition by heat, the kiln being meanwhile rotated to agglomerate the ore into small homogeneous lumps, and then compressing such lumps into larger lumps or blocks.

BATTERY SCREEN-FRAME FOR QUARTZ-MILLS.—No. 889,380. Robert E. L. Lampson, Jamestown, California.



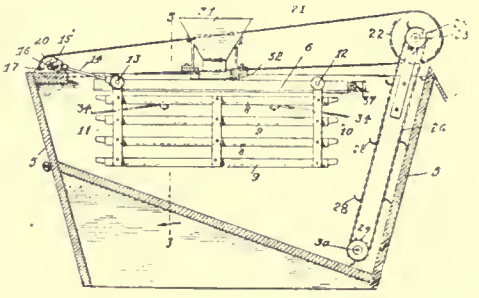
In a device of the character described a main frame, strips along one edge and both ends of the face of said main frame, the inner edge of said strips being beveled inward, auxiliary frames having outwardly beveled edges adapted to be inserted under said first named beveled edges, means at the ends beyond the perforations; and means to move tween said main and auxiliary frames as described.

SLIME-SAVING DEVICE FOR ORE-CONCENTRATORS. No. 889,300. Bert E. Duggan, Telluride, Colorado.



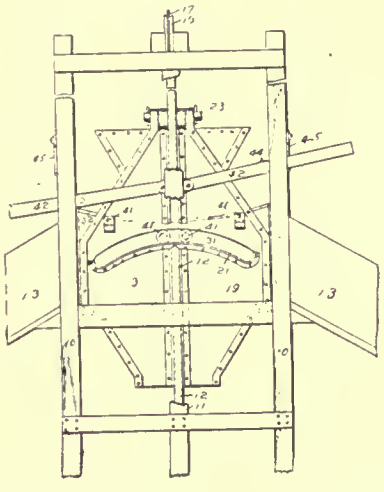
The combination of a stationary frame, a movable frame, a concentrator table arranged upon said movable frame, a pair of cross-bars arranged above the table and having their ends formed with threaded apertures, nuts arranged upon the main frame, upright screw-rods having centrally arranged flattened enlargements and oppositely screw-threaded ends, their upper ends being engaged with apertures in the cross-bars and their lower ends with said nuts, a slime-skimming device arranged above the table and having a Y-shaped body, one of its branches being trough-shaped to provide a discharge spout and its other two branches being angular in cross-section and having horizontal flanges engaged with the bottom faces of said cross-bars, and bolts securing said flanges to the cross-bars, substantially as set forth.

GOLD-SAVING MACHINE.—No. 890,059. Thomas Hussey, Hollywood, California.



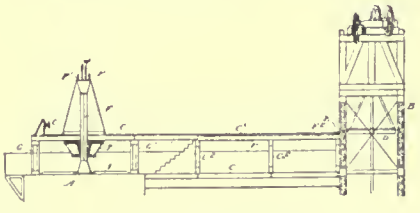
In a gold-saving machine a concentrator pan having a corrugated bottom provided with perforations in the apices near the ends thereof, said bottom being turned upwardly at the ends beyond the perforations; and means to move said pan horizontally in the directions that the corrugations run.

MINE-ELEVATOR.—No. 890,124. William Channon, Des Moines, Iowa.



In a device of the class described, the combination of an elevator cage, a platform tiltingly mounted in the cage, an elevator guide terminating at the dumping point, two rollers fixed to the tilting platform and extended outwardly beyond the side of the cage, and in engagement with the opposite sides of said guide, and weighted levers pivoted in the path of the dumping platform and arranged to be engaged by the dumping platform when the rollers reach the end of the guide to thereby tilt the platform, and to yield sufficiently when engaged by the tilting platform to prevent breakage and undue strain upon the parts, and means for holding said weighted levers in elevated positions.

BLAST-FURNACE CHARGING APPARATUS.—No. 888,723. David I. Miller, Sheffield, Alabama.



In a blast-furnace charging apparatus, the combination of a blast-furnace having a hopper and bell, a charging bridge, a horizontally disposed track elevated above the charging bridge and projecting over the blast-furnace hopper, a charge-distributer interposed between the elevated track and the blast-furnace hopper, an elevator having a track section, and a movable or floating track section interposed between the elevated bridge track and the elevator track section.

MINE REPORTS.

ANACONDA COPPER MINING CO., BUTTE, MONTANA.

The mines and reduction works of the Anaconda Copper Mining Co. were operated fully from the beginning of the year until September 1, except for some interferences resulting from extreme cold weather, which delayed transportation of ore and fuel during the months of January, February, and March. The condition of the metal market and the accumulation of unsold product, commencing with July, made it desirable, in the opinion of the trustees, to restrict the expenditures and the output of copper until such time as the market would absorb the product, and commencing with September the production was sharply curtailed, until it reached as low a point as 35% of the normal. General business and financial conditions throughout the country later preventing any recovery in the market for metals, and the low rate of production making necessary increased costs of copper, it was decided at the beginning of December to close the mines and works of the company entirely, until conditions should show improvement. The high price of copper prevailing during the first six months of the year made it seem advisable to treat ores of a lower grade than had been extracted in any previous period in the Company's history. Much of the product resulting from the treatment of these ores was not marketed until the late months of the year, when the price of copper had receded to a point where the profit on this production was much smaller than had been anticipated, as the product of ores mined as early in the year as March was not sold until the latter part of the year, at prices 10 to 12 c. per lb. lower than were ruling at the time the ore was extracted. The copper on hand at the end of the year was produced during the period of curtailment and cost $163,105 in excess of the amount realized from its sale. In order to keep this loss in the year during which it was made, the amount has been deducted from the profits of the year, as shown by the profit and loss statement. All these conditions have resulted in a profit very much less than anticipated at the beginning of the year. Out of surplus for the preceding year and profits for 1907 dividends were declared amounting to $6,300,000.

The mines and works of the company were not in operation during January and February. In the early part of March work was again started, and in the latter part of the month production had about reached the normal. The production figures and rough costs for March and April show a considerably higher grade of ore and a lower cost per pound of copper than have been realized at any time during the last few years. Early in the year 1907 it was considered advisable to grant a general advance in wages; contracts were entered into with labor unions holding in their membership nearly all of the employees of the company. These contracts provided for an advance in wages during the time when high prices prevailed for copper, and in the month of October, the price having receded below the dividing line, wages in all departments of mining and smelting were reduced, in accordance with the contracts, to the scale prevailing early in 1906. The contracts made with the labor unions were complied with in all respects, without any attempt at evasion on the part of either party.

Considerable development was done in most of the mines of the company during the year, the large part of it being lateral development; the only shaft deepened during the year being the High Ore, which was sunk 293 ft., the depth at the close of the year being 2880 ft. A station has been cut on the 2800-ft. level, but no development of the veins has been made below the 2600-ft. level. At the time of the last annual report the main Anaconda vein had been cut and levels driven on the 2000-ft. level of the St. Lawrence, 2200 and 2400 of the Anaconda, and the 2200 of the Never Sweat. There has been practically no stoping done on these levels during the year past, but at the time of resumption of operations in March stoping at various points on these levels was commenced, as it is desirable now to mine a higher grade of ore than during the early part of the year 1907. The South vein in the Anaconda group has been opened on the 1800, 2000, and 2200-ft. levels of the Anaconda, and for the entire distance developed the vein shows good width of ore, one-half of which is apparently smelting grade. In the St. Lawrence mine in the upper levels a new vein has been opened for a distance of 500 ft., showing ore of good concentrating grade.

Electric locomotives have been installed on several important levels of the Anaconda group and are giving satisfactory results in efficiency and cost of haulage. A new compressor building was erected at the Diamond mine and the plant is now in full operation. It contains four electrically driven air-compressors, with a total capacity of 16,000 cu. ft. of air per minute, all fitted with steam cylinders for use in case of failure of electric current. The compressors were taken from different mines, and only two new low-pressure cylinders of 38¼ by 48-in. were added. Four new 600-hp. alternating-current electric motors, two circulating pumps, and four 5-ton traveling cranes were purchased and installed. The Never Sweat compressor-plant now consists of five compressors, with a capacity of 32,000 cu. ft. of air per minute, two of the largest being electrically driven. This plant is connected with the Diamond plant by a water-pipe, so that water can be pumped from one plant to another, and the two are connected with all of the mines of the company and the compressor plants of the Boston & Montana Co., so that in case of accident at any of the most important

PROFIT AND LOSS ACCOUNT OF YEAR ENDING DECEMBER 31, 1907.

Copper, silver, and gold on hand at beginning of year—copper at cost, silver and gold at selling price	$ 5,306,003.08	Sales of copper, silver, and gold, that is, deliveries to customers	$12,038,714.69
Mining expenses, including development and depreciation	5,241,704.28	Royalties	38,830.92
Ore, matte, and copper purchases, including transportation and purchasing expenses	210,630.33	Dividends on investments	33,553.00
Transportation of ore from mines to reduction works	153,139.99	Rental of water-rights	50,000.00
Reduction expenses at Anaconda, including depreciation	3,640,295.47	Miscellaneous receipts	6,109.96
Transportation of metals from west to east, refining and selling expenses	997,938.75	Net profit of subsidiary departments, after deducting depletion of coal and timber lands and depreciation of plants and equipment	581,281.74
Administration expenses	53,648.59	Copper, silver, and gold on hand at end of year—copper at cost, silver and gold at selling price, $6,165,748.78; less loss on realization of copper on hand, $163,105.33	6,002,643.45
Balance, being profit before dealing with interest, carried down	3,147,773.27		
	$18,751,133.76		$18,751,133.76
Balance, being profit, carried to balance sheet	$ 3,378,220.42	Balance brought down	$ 3,147,773.27
		Interest	230,447.15
	$ 3,378,220.42		$ 3,378,220.42

compressor plants of the district, air can be furnished by the others to keep the mines in operation.

The mines of the Company produced during the year 1,123,692 wet tons of ore. The reduction works treated for all companies during the year 2,582,611 dry tons of ore and other copper-bearing material. Of this, 1,110,203 tons of ore from the mines, 2966 tons of concentrate, 16,250 tons of slime, and 24,226 tons of slag from the old works was treated for the Company, from which there was produced 63,055,661 lb. fine copper.

Since February, 1907, electric power has been used at the concentrator and in other departments of the works. This power has been found efficient, and the cost much below that of steam for the same work. The large part of the electric power furnished at the works is brought from the Missouri river, but during the year the Flint creek water-power and electric plant has been furnishing a considerable amount of current, and the Washoe Co. installed in its sub-station at the works three 400-kw. transformers, one voltage regulator for the city lighting system, and additional switchboard capacity for the new blast-furnace blower-house. In the smelter power-house there were installed one 600-hp. motor, one 750-hp. motor for blowing engines, and one 600-hp. motor for a air-compressor. An entire new blower-building was constructed, with 15-ton crane for handling machinery, four 600-hp. motors, and four blowers, each with a capacity of 36,000 cu. ft. of air per minute. This plant was just about ready for operation at the time of suspension of work late in the year. The McDougall building was extended, and eight additional roasters with equipment were completed.

NUNDYDROOG CO., LTD., OORGAUM, SOUTH INDIA

The Nundydroog Co., Ltd., paid its first dividend on October 18, 1888, amounting to £25,840. The earnings rapidly increased, under the efficient direction of John Taylor & Sons, the consulting engineers to the company, so that, including the last dividend of £99,050, distributed on March 20 last, the total return to the shareholders in 27 years has been £1,340,076. During the year 1907 the mills of the Company treated 84,000 tons of ore, producing 66,696 oz. gold, and there was cyanided 83,970 tons of old tailing, yielding 8268 oz. gold. The gold bullion yielded £283,138, included in which is £1607 received for gold obtained from slags and crucibles, representing 0.56% of the total. The number of employees working on December 1, 1907, was 3918, of whom only 70 were Europeans. Among the natives employed were 238 women, these being engaged in such work as tramming, charging and discharging cyanide vats, helping on construction, and sweeping. The development work for the year has demonstrated the extension of the vein to a depth of 2150 ft., and has added 38,640 tons to the ore reserves, bringing up the aggregate to 111,640 tons, or about one and one-third year's supply at the present rate of milling. The mill, containing 80 stamps, weighing 840 lb. each, made 346½ days' time during the year, with an average stamp-duty of 3.03 tons per stamp per diem, crushing to 30 mesh. The recovery of gold per ton of ore milled was 0.793 oz. worth $16.39, U. S. Cy. and the total costs were $7.84, showing a gross profit of $8.55 per ton. Analysis of costs of operation are not given, the minutiae of the reports dealing with mine development. While this accentuates the point of first importance, which is too often ignored by directors content to believe that they have a mine on which they may depend detail as to the metallurgical work is also interesting and useful. The company proposes in future to provide all capital expenditure out of profits, instead of issuing fresh capital for improvements as in the past. The expenditures for betterments during 1907 amounted to £14,751. Power for the operations of the Company is developed electrically, a contract having been made a little over a year ago, whereby 911 hp. are delivered at a cost of £10 per horse-power per annum. Previously power cost £24 for the same unit. There were some interruptions in the delivery of power during the year owing to shortage of water. The average normal rainfall in the district is 30.94 in. During 1907 the precipitation was only 22.41 inches.

Decisions Relating to Mining.

Specially reported for the MINING AND SCIENTIFIC PRESS.

DEFINITIONS OF LODE AND PLACER LOCATIONS.

A lode location is the location of a vein or lode in mineral-bearing rock or other earthy matter in place in a fissure in rock, so that its boundaries are sharply defined by rocky walls in place. A placer location is a location of a tract of land for the mineral-bearing or other valuable deposits upon or within it, that are not found in lodes or veins in rock in place; and is a claim of a tract of land for the sake of loose deposits on or near its surface.

Webb *v.* American Asphaltum Mining Co., 157 Fed. 203, Nov., '07.

METALLIFEROUS AND NON-METALLIFEROUS SUBSTANCES.

Section 2320 of the U. S. statute specifies the method by which veins or lodes of quartz or other rock in place bearing gold, silver, cinnabar, lead, tin, copper, or other valuable deposits, may be entered and patented. And the terms, "all mineral deposits," or "other valuable deposits," include non-metalliferous deposits, such as alum, asphaltum, borax, guano, diamonds, gypsum, resin, marble, mica, slate, amber, petroleum, limestone, and building stone, as well as metalliferous metal, such as gold, silver, and other metals.

Webb *v.* American Asphaltum Mining Co., 157 Fed. 203, Nov., '07.

DUTY OF SHOT-FIRER—CONTRIBUTORY NEGLIGENCE.

The statute of Missouri requiring the shot-firer, on discovering that a drill-hole is gripping too much, or that it is drilled too much into the tight, so that it may, in his judgment, prove dangerous, to pass it without firing and promptly notify the mine foreman, only imposes diligence and caution on the shot-firer, and does not necessarily make him negligent in failing to discover the danger in a shot fired by him.

Kirby *v.* Manufacturers' Coal & Coke Co., (Mo. App.) 106 Southwest. 1069, Dec., '07.

COAL LANDS—TAXATION.

A tract of coal land of more than 1000 acres was leased for 100 years, a period supposed to be necessary under present conditions to mine and market the coal. Under existing circumstances it was not practicable to mine more than 85 acres annually, or 170 acres during an assessment period of two years. Under the assessment laws of Virginia that amount only should have been assessed for taxes as "improved and under development."

Commonwealth *v.* Pocahontas Coal & Coke Co., (Va.) 60 Southeast. 84, Jan., '08.

LOCATION OF MINING CLAIM—ABANDONMENT—RE-LOCATION.

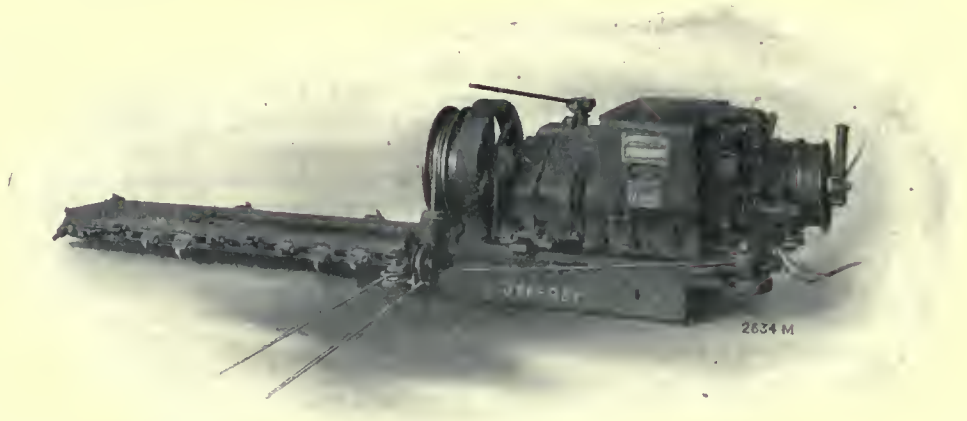
The United States statutes authorize a discoverer to locate a mining claim, and require the sinking of a discovery shaft before the expiration of 90 days from the posting of the notices of location; they also provide that locators of mining claims complying with the laws shall have the exclusive right of possession and enjoyment of all the surface included within the lines of location, and all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface-lines extending downward vertically within planes drawn through parallel end-lines; and that the location must be distinctly marked on the ground, so that its boundaries can be readily traced, and that until a patent has been issued not less than a specified amount of work shall be performed each year, or the claim may be open to re-location. Under these statutes a junior location made on ground covered by a valid existing senior location will not prevail over a location on the same ground, made after a failure to do the work on the senior location. Such a re-location is not affected by the statute under which the claimant, by failure to assert his rights acquired, may lose them.

Nash *v.* McNamara, (Nev.) 93 Pac. 405, Jan., '08.

SHORTWALL COAL CUTTER FOR ROOM AND PILLAR.

The economy and speed with which coal is mined by longwall machines have given rise to a very large demand for an efficient machine operating on the longwall plan for room and pillar work. To meet this need the Jeffrey Mfg. Co. has added to its line of electric coal cutters a new room and pillar machine, known as the Jeffrey 26-B Shortwall Coal Cutter, illustrations of which are shown herewith. The difference between this and the well known breast machine is largely in the method of cutting. The new type cuts across the face of the coal, starting at one side of the room and not stopping until it finishes the cut at the other side.

A ½-in. steel feed-cable wound upon a power-driven drum at the front end of the machine pulls it across the face of the coal at a speed dependent upon, and suited to, the hardness of the cutting and the nature of the coal or clay in which the cutting is done. This drum when desired can be disengaged by means of a suitable clutch, so that the machine in finishing its cut at the left-hand rib may be angled for the purpose of maintaining a uniform width of room. Another cable, having no connection whatever with the power, is arranged to act as a guide to hold the machine to its work at the proper angle for its greatest cutting efficiency. Suitable sheave wheels are provided at convenient points on the machine to guide the feed-cable so that it can be led off in any direction, thereby enabling the machine



to be loaded, unloaded, moved about, and pulled out from under the coal by its own power, a desirable feature which strongly appeals to the machine-runners. The gearing is arranged so that the feed-drum may be operated at a sufficiently high speed to move the machine quickly about the working place. To meet conditions of heavy service, an exceptionally powerful compound-wound motor is provided. The operation of the machine may be briefly described as follows: It is brought into the room on a truck, moved by its own power or hauled by a mule. A pipe-jack is placed at the face of the coal at the right-hand rib and the feed-cable attached. The motor is then started and the machine moved to the face of the coal. A simple guiding device, consisting of a piece of tee-rail and one jack, is then set up on the left-hand side of the machine and the 'sumping cut' started, the feed-cable pulling the cutting-frame in under the coal and the guiding device serving to hold the machine in line. When the sumping cut is completed, a steel anchor-hook is secured by a wedge in the left-hand rib near the face, to which are hooked one end each of both the guide and feed cables which lead across the face of the coal. The cable is then attached to a jack set up at the right-hand rib in line with the rear drums, and the machine started across the room. In operation, the feed-cable pulls the machine across the coal face, and the guide-cable keeps it at the proper angle to the face of the coal.

A flexible brand of wire with elliptic strands is used for the feed and guide cables, eliminating any tendency to kink or curl when the tension is released, and materially increasing the wearing surfaces of the cable. The elasticity of the cable equalizes the shocks and jars on the machine and gives the motor an even steady load.

When the machine reaches the left-hand rib, the pipe-jack is moved to a position near the truck, the feed-cable attached, the machine pulled out from under the coal and over to the truck, where it is loaded by its own power and is ready to move to the next working place.

COMMERCIAL PARAGRAPHS.

BAINBRIDGE, SEYMOUR & CO. are removing their offices from 1 St. Helens Place, to Salisbury House, London.

W. A. STADELMAN, recently sales manager of the Wellman-Seaver-Morgan Co., is now vice-president of the DARLEY ENGINEERING CO., 80 Broadway, New York.

C. G. PATTERSON, of the BUTTERS VACUUM FILTER CO., is at Goldfield, Nevada, installing the Butters system of filters in the Goldfield Consolidated and Florence mills.

THE DARLEY ENGINEERING CO., Chicago, has issued a small pamphlet illustrating and describing its vacuum process of removing ashes and clinkers from boiler-rooms and furnaces.

THE DEISTER CONCENTRATOR CO., Fort Wayne, Indiana, has one of its slime-tables installed in the Combination mill, Goldfield, Nevada, where it is undergoing a test as to effectiveness and capacity.

THE CYCLONE DRILL CO., Orrville, Ohio, has issued a small booklet which it calls 'Does Well Drilling Pay?' and which will be sent free to any address. The pamphlet discusses the business of well drilling from the standpoint of the prospective driller.

THE PEMBERTHY INJECTOR CO., Detroit, Michigan, advises us that, beginning with the July issue, the *Engineer and Fireman* will be increased from a 32 to an 80 page magazine. Free sample copy will be mailed to any reader of the MINING AND SCIENTIFIC PRESS upon request.

PUBLICATIONS RECEIVED.
